Abstract

This documentation collection provides instructions on how to monitor and optimize the throughput, latency, and power consumption of Red Hat Enterprise Linux 8 in different scenarios.

Table of Contents

MAKING OPEN SOURCE MORE INCLUSIVE	9
PROVIDING FEEDBACK ON RED HAT DOCUMENTATION	10
CHAPTER 1. OVERVIEW OF PERFORMANCE MONITORING OPTIONS	11
CHAPTER 2. GETTING STARTED WITH TUNED	13
2.1. THE PURPOSE OF TUNED	13
2.2. TUNED PROFILES	13
Syntax of profile configuration	13
2.3. THE DEFAULT TUNED PROFILE	14
2.4. MERGED TUNED PROFILES	14
2.5. THE LOCATION OF TUNED PROFILES	15
2.6. TUNED PROFILES DISTRIBUTED WITH RHEL	15
2.7. TUNED CPU-PARTITIONING PROFILE	17
2.8. USING THE TUNED CPU-PARTITIONING PROFILE FOR LOW-LATENCY TUNING	18
2.9. CUSTOMIZING THE CPU-PARTITIONING TUNED PROFILE	19
2.10. REAL-TIME TUNED PROFILES DISTRIBUTED WITH RHEL	20
2.11. STATIC AND DYNAMIC TUNING IN TUNED	20
2.12. TUNED NO-DAEMON MODE	21
2.13. INSTALLING AND ENABLING TUNED	21
2.14. LISTING AVAILABLE TUNED PROFILES	22
2.15. SETTING A TUNED PROFILE	23
2.16. DISABLING TUNED	24
CHAPTER 3. CUSTOMIZING TUNED PROFILES	25
3.1. TUNED PROFILES	25
Syntax of profile configuration	25
3.2. THE DEFAULT TUNED PROFILE	25
3.3. MERGED TUNED PROFILES	26
3.4. THE LOCATION OF TUNED PROFILES	26
3.5. INHERITANCE BETWEEN TUNED PROFILES	27
3.6. STATIC AND DYNAMIC TUNING IN TUNED	27
3.7. TUNED PLUG-INS	28
Syntax for plug-ins in TuneD profiles	29
Short plug-in syntax	29
Conflicting plug-in definitions in a profile	30
3.8. AVAILABLE TUNED PLUG-INS	30
Monitoring plug-ins	30
Tuning plug-ins	30
3.9. VARIABLES IN TUNED PROFILES	34
3.10. BUILT-IN FUNCTIONS IN TUNED PROFILES	35
3.11. BUILT-IN FUNCTIONS AVAILABLE IN TUNED PROFILES	35
3.12. CREATING NEW TUNED PROFILES	36
3.13. MODIFYING EXISTING TUNED PROFILES	37
3.14. SETTING THE DISK SCHEDULER USING TUNED	38
CHAPTER 4. REVIEWING A SYSTEM USING TUNA INTERFACE	41
4.1. INSTALLING TUNA TOOL	41
4.2. VIEWING THE SYSTEM STATUS USING TUNA TOOL	41
4.3. TUNING CPUS USING TUNA TOOL	42
4.4. TUNING IRQS USING TUNA TOOL	44

CHAPTER 5. MONITORING PERFORMANCE USING RHEL SYSTEM ROLES	46
5.1. INTRODUCTION TO RHEL SYSTEM ROLES	46
5.2. RHEL SYSTEM ROLES TERMINOLOGY	46
5.3. INSTALLING RHEL SYSTEM ROLES IN YOUR SYSTEM	47
5.4. APPLYING A ROLE	48
5.5. INTRODUCTION TO THE METRICS SYSTEM ROLE	50
5.6. USING THE METRICS SYSTEM ROLE TO MONITOR YOUR LOCAL SYSTEM WITH VISUALIZATION	51
5.7. USING THE METRICS SYSTEM ROLE TO SETUP A FLEET OF INDIVIDUAL SYSTEMS TO MONITOR THEMSELVES	52
5.8. USING THE METRICS SYSTEM ROLE TO MONITOR A FLEET OF MACHINES CENTRALLY VIA YOUR LOCAL MACHINE	53
5.9. SETTING UP AUTHENTICATION WHILE MONITORING A SYSTEM USING THE METRICS SYSTEM ROLE	53
5.10. USING THE METRICS SYSTEM ROLE TO CONFIGURE AND ENABLE METRICS COLLECTION FOR SQL SERVER	54
CHAPTER 6. SETTING UP PCP	56
6.1. OVERVIEW OF PCP	56
6.2. INSTALLING AND ENABLING PCP	56
6.3. DEPLOYING A MINIMAL PCP SETUP	57
6.4. SYSTEM SERVICES DISTRIBUTED WITH PCP	58
6.5. TOOLS DISTRIBUTED WITH PCP	59
6.6. PCP DEPLOYMENT ARCHITECTURES	62
6.7. RECOMMENDED DEPLOYMENT ARCHITECTURE	65
6.8. SIZING FACTORS	65
6.9. CONFIGURATION OPTIONS FOR PCP SCALING	66
6.10. EXAMPLE: ANALYZING THE CENTRALIZED LOGGING DEPLOYMENT	66
6.11. EXAMPLE: ANALYZING THE FEDERATED SETUP DEPLOYMENT	67
6.12. TROUBLESHOOTING HIGH MEMORY USAGE	68
CHAPTER 7. LOGGING PERFORMANCE DATA WITH PMLOGGER	71
7.1. MODIFYING THE PMLOGGER CONFIGURATION FILE WITH PMLOGCONF	71
7.2. EDITING THE PMLOGGER CONFIGURATION FILE MANUALLY	71
7.3. ENABLING THE PMLOGGER SERVICE	72
7.4. SETTING UP A CLIENT SYSTEM FOR METRICS COLLECTION	73
7.5. SETTING UP A CENTRAL SERVER TO COLLECT DATA	74
7.6. REPLAYING THE PCP LOG ARCHIVES WITH PMREP	75
CHAPTER 8. MONITORING PERFORMANCE WITH PERFORMANCE CO-PILOT	77
8.1. MONITORING POSTFIX WITH PMDA-POSTFIX	77
8.2. VISUALLY TRACING PCP LOG ARCHIVES WITH THE PCP CHARTS APPLICATION	78
8.3. COLLECTING DATA FROM SQL SERVER USING PCP	80
CHAPTER 9. PERFORMANCE ANALYSIS OF XFS WITH PCP	83
9.1. INSTALLING XFS PMDA MANUALLY	83
9.2. EXAMINING XFS PERFORMANCE METRICS WITH PMINFO	83
9.3. RESETTING XFS PERFORMANCE METRICS WITH PMSTORE	85
9.4. PCP METRIC GROUPS FOR XFS	85
9.5. PER-DEVICE PCP METRIC GROUPS FOR XFS	87
CHAPTER 10. SETTING UP GRAPHICAL REPRESENTATION OF PCP METRICS	89
10.1. SETTING UP PCP WITH PCP-ZEROCONF	89
10.2. SETTING UP A GRAFANA-SERVER	89
10.3. ACCESSING THE GRAFANA WEB UI	90
10.4. CONFIGURING PCP REDIS	91

10.5. CREATING PANELS AND ALERT IN PCP REDIS DATA SOURCE	93
10.6. ADDING NOTIFICATION CHANNELS FOR ALERTS	95
10.7. SETTING UP AUTHENTICATION BETWEEN PCP COMPONENTS	96
10.8. INSTALLING PCP BPFTRACE	97
10.9. VIEWING THE PCP BPFTRACE SYSTEM ANALYSIS DASHBOARD	98
10.10. INSTALLING PCP VECTOR	99
10.11. VIEWING THE PCP VECTOR CHECKLIST	100
10.12. TROUBLESHOOTING GRAFANA ISSUES	101
CHAPTER 11. OPTIMIZING THE SYSTEM PERFORMANCE USING THE WEB CONSOLE	104
11.1. PERFORMANCE TUNING OPTIONS IN THE WEB CONSOLE	104
11.2. SETTING A PERFORMANCE PROFILE IN THE WEB CONSOLE	104
11.3. MONITORING PERFORMANCE USING THE WEB CONSOLE	105
CHAPTER 12. SETTING THE DISK SCHEDULER	107
12.1. AVAILABLE DISK SCHEDULERS	107
12.2. DIFFERENT DISK SCHEDULERS FOR DIFFERENT USE CASES	108
12.3. THE DEFAULT DISK SCHEDULER	108
12.4. DETERMINING THE ACTIVE DISK SCHEDULER	108
12.5. SETTING THE DISK SCHEDULER USING TUNED	109
12.6. SETTING THE DISK SCHEDULER USING UDEV RULES	110
12.7. TEMPORARILY SETTING A SCHEDULER FOR A SPECIFIC DISK	111
CHAPTER 13. TUNING THE PERFORMANCE OF A SAMBA SERVER	113
13.1. SETTING THE SMB PROTOCOL VERSION	113
13.2. TUNING SHARES WITH DIRECTORIES THAT CONTAIN A LARGE NUMBER OF FILES	113
13.3. SETTINGS THAT CAN HAVE A NEGATIVE PERFORMANCE IMPACT	114
CHAPTER 14. OPTIMIZING VIRTUAL MACHINE PERFORMANCE	115
14.1. WHAT INFLUENCES VIRTUAL MACHINE PERFORMANCE	115
The impact of virtualization on system performance	115
Reducing VM performance loss	115
14.2. OPTIMIZING VIRTUAL MACHINE PERFORMANCE USING TUNED	116
14.3. CONFIGURING VIRTUAL MACHINE MEMORY	117
14.3.1. Adding and removing virtual machine memory using the web console	117
14.3.2. Adding and removing virtual machine memory using the command-line interface	118
14.3.3. Additional resources	120
14.4. OPTIMIZING VIRTUAL MACHINE I/O PERFORMANCE	120
14.4.1. Tuning block I/O in virtual machines	120
14.4.2. Disk I/O throttling in virtual machines	121
14.4.3. Enabling multi-queue virtio-scsi	122
14.5. OPTIMIZING VIRTUAL MACHINE CPU PERFORMANCE	122
14.5.1. Adding and removing virtual CPUs using the command-line interface	123
14.5.2. Managing virtual CPUs using the web console	124
14.5.3. Configuring NUMA in a virtual machine	125
14.5.4. Sample vCPU performance tuning scenario	127
14.5.5. Deactivating kernel same-page merging	133
14.6. OPTIMIZING VIRTUAL MACHINE NETWORK PERFORMANCE	133
14.7. VIRTUAL MACHINE PERFORMANCE MONITORING TOOLS	134
14.8. RELATED INFORMATION	136
CHAPTER 15. IMPORTANCE OF POWER MANAGEMENT	137
15.1. POWER MANAGEMENT BASICS	137
15.2. AUDIT AND ANALYSIS OVERVIEW	138

15.3. TOOLS FOR AUDITING	139
CHAPTER 16. MANAGING POWER CONSUMPTION WITH POWERTOP	143
16.1. THE PURPOSE OF POWERTOP	143
16.2. USING POWERTOP	143
16.2.1. Starting PowerTOP	143
16.2.2. Calibrating PowerTOP	143
16.2.3. Setting the measuring interval	144
16.2.4. Related information	144
16.3. POWERTOP STATISTICS	144
16.3.1. The Overview tab	144
16.3.2. The Idle stats tab	145
16.3.3. The Device stats tab	145
16.3.4. The Tunables tab	145
16.4. WHY POWERTOP DOES NOT DISPLAY FREQUENCY STATS VALUES IN SOME INSTANCES	146
16.5. GENERATING AN HTML OUTPUT	146
16.6. OPTIMIZING POWER CONSUMPTION	147
16.6.1. Optimizing power consumption using the powertop service	147
16.6.2. The powertop2tuned utility	147
16.6.3. Optimizing power consumption using the powertop2tuned utility	147
16.6.4. Comparison of powertop.service and powertop2tuned	148
CHAPTER 17. TUNING CPU FREQUENCY TO OPTIMIZE ENERGY CONSUMPTION	149
17.1. SUPPORTED CPUPOWER TOOL COMMANDS	149
17.2. CPU IDLE STATES	150
17.3. OVERVIEW OF CPUFREQ	151
17.3.1. CPUfreq drivers	151
17.3.2. Core CPUfreq governors	152
17.3.3. Intel P-state CPUfreq governors	153
17.3.4. Setting up CPUfreq governor	154
CHAPTER 18. GETTING STARTED WITH PERF	156
18.1. INTRODUCTION TO PERF	156
18.2. INSTALLING PERF	156
18.3. COMMON PERF COMMANDS	156
CHAPTER 19. PROFILING CPU USAGE IN REAL TIME WITH PERF TOP	158
19.1. THE PURPOSE OF PERF TOP	158
19.2. PROFILING CPU USAGE WITH PERF TOP	158
19.3. INTERPRETATION OF PERF TOP OUTPUT	159
19.4. WHY PERF DISPLAYS SOME FUNCTION NAMES AS RAW FUNCTION ADDRESSES	159
19.5. ENABLING DEBUG AND SOURCE REPOSITORIES	159
19.6. GETTING DEBUGINFO PACKAGES FOR AN APPLICATION OR LIBRARY USING GDB	160
CHAPTER 20. COUNTING EVENTS DURING PROCESS EXECUTION WITH PERF STAT	162
20.1. THE PURPOSE OF PERF STAT	162
20.2. COUNTING EVENTS WITH PERF STAT	162
20.3. INTERPRETATION OF PERF STAT OUTPUT	163
20.4. ATTACHING PERF STAT TO A RUNNING PROCESS	164
CHAPTER 21. RECORDING AND ANALYZING PERFORMANCE PROFILES WITH PERF	165
21.1. THE PURPOSE OF PERF RECORD	165
21.2. RECORDING A PERFORMANCE PROFILE WITHOUT ROOT ACCESS	165
21.3. RECORDING A PERFORMANCE PROFILE WITH ROOT ACCESS	165
21.4. RECORDING A PERFORMANCE PROFILE IN PER-CPU MODE	166

21.5. CAPTURING CALL GRAPH DATA WITH PERF RECORD	166
21.6. ANALYZING PERF.DAT WITH PERF REPORT	167
21.7. INTERPRETATION OF PERF REPORT OUTPUT	168
21.8. GENERATING A PERF.DAT FILE THAT IS READABLE ON A DIFFERENT DEVICE	168
21.9. ANALYZING A PERF.DAT FILE THAT WAS CREATED ON A DIFFERENT DEVICE	169
21.10. WHY PERF DISPLAYS SOME FUNCTION NAMES AS RAW FUNCTION ADDRESSES	170
21.11. ENABLING DEBUG AND SOURCE REPOSITORIES	170
21.12. GETTING DEBUGINFO PACKAGES FOR AN APPLICATION OR LIBRARY USING GDB	171
CHAPTER 22. INVESTIGATING BUSY CPUS WITH PERF	173
22.1. DISPLAYING WHICH CPU EVENTS WERE COUNTED ON WITH PERF STAT	173
22.2. DISPLAYING WHICH CPU SAMPLES WERE TAKEN ON WITH PERF REPORT	173
22.3. DISPLAYING SPECIFIC CPUS DURING PROFILING WITH PERF TOP	174
22.4. MONITORING SPECIFIC CPUS WITH PERF RECORD AND PERF REPORT	174
CHAPTER 23. MONITORING APPLICATION PERFORMANCE WITH PERF	176
23.1. ATTACHING PERF RECORD TO A RUNNING PROCESS	176
23.2. CAPTURING CALL GRAPH DATA WITH PERF RECORD	176
23.3. ANALYZING PERF.DAT WITH PERF REPORT	177
CHAPTER 24. CREATING UPROBES WITH PERF	179
24.1. CREATING UPROBES AT THE FUNCTION LEVEL WITH PERF	179
24.2. CREATING UPROBES ON LINES WITHIN A FUNCTION WITH PERF	179
24.3. PERF SCRIPT OUTPUT OF DATA RECORDED OVER UPROBES	180
CHAPTER 25. PROFILING MEMORY ACCESSES WITH PERF MEM	181
25.1. THE PURPOSE OF PERF MEM	181
25.2. SAMPLING MEMORY ACCESS WITH PERF MEM	181
25.3. INTERPRETATION OF PERF MEM REPORT OUTPUT	183
CHAPTER 26. DETECTING FALSE SHARING	185
26.1. THE PURPOSE OF PERF C2C	185
26.2. DETECTING CACHE-LINE CONTENTION WITH PERF C2C	185
26.3. VISUALIZING A PERF.DAT FILE RECORDED WITH PERF C2C RECORD	186
26.4. INTERPRETATION OF PERF C2C REPORT OUTPUT	188
26.5. DETECTING FALSE SHARING WITH PERF C2C	189
CHAPTER 27. GETTING STARTED WITH FLAMEGRAPHS	192
27.1. INSTALLING FLAMEGRAPHS	192
27.2. CREATING FLAMEGRAPHS OVER THE ENTIRE SYSTEM	192
27.3. CREATING FLAMEGRAPHS OVER SPECIFIC PROCESSES	193
27.4. INTERPRETING FLAMEGRAPHS	194
CHAPTER 28. MONITORING PROCESSES FOR PERFORMANCE BOTTLENECKS USING PERF CIRCULAR BUFFERS	196
28.1. CIRCULAR BUFFERS AND EVENT-SPECIFIC SNAPSHOTS WITH PERF	196
28.2. COLLECTING SPECIFIC DATA TO MONITOR FOR PERFORMANCE BOTTLENECKS USING PERF CIRCULAR BUFFERS	196
CHAPTER 29. ADDING AND REMOVING TRACEPOINTS FROM A RUNNING PERF COLLECTOR WITHOUT STOPPING OR RESTARTING PERF	198
29.1. ADDING TRACEPOINTS TO A RUNNING PERF COLLECTOR WITHOUT STOPPING OR RESTARTING PERF	198
29.2. REMOVING TRACEPOINTS FROM A RUNNING PERF COLLECTOR WITHOUT STOPPING OR RESTARTING PERF	199

CHAPTER 30. PROFILING MEMORY ALLOCATION WITH NUMASTAT	200
30.1. DEFAULT NUMASTAT STATISTICS	200
30.2. VIEWING MEMORY ALLOCATION WITH NUMASTAT	200
CHAPTER 31. CONFIGURING AN OPERATING SYSTEM TO OPTIMIZE CPU UTILIZATION	202
31.1. TOOLS FOR MONITORING AND DIAGNOSING PROCESSOR ISSUES	202
31.2. TYPES OF SYSTEM TOPOLOGY	203
31.2.1. Displaying system topologies	203
31.3. CONFIGURING KERNEL TICK TIME	205
31.4. OVERVIEW OF AN INTERRUPT REQUEST	207
31.4.1. Balancing interrupts manually	207
31.4.2. Setting the smp_affinity mask	208
CHAPTER 32. TUNING SCHEDULING POLICY	210
32.1. CATEGORIES OF SCHEDULING POLICIES	210
32.2. STATIC PRIORITY SCHEDULING WITH SCHED_FIFO	210
32.3. ROUND ROBIN PRIORITY SCHEDULING WITH SCHED_RR	211
32.4. NORMAL SCHEDULING WITH SCHED_OTHER	211
32.5. SETTING SCHEDULER POLICIES	211
32.6. POLICY OPTIONS FOR THE CHRT COMMAND	212
32.7. CHANGING THE PRIORITY OF SERVICES DURING THE BOOT PROCESS	213
32.8. PRIORITY MAP	214
32.9. TUNED CPU-PARTITIONING PROFILE	215
32.10. USING THE TUNED CPU-PARTITIONING PROFILE FOR LOW-LATENCY TUNING	216
32.11. CUSTOMIZING THE CPU-PARTITIONING TUNED PROFILE	217
CHAPTER 33. FACTORS AFFECTING I/O AND FILE SYSTEM PERFORMANCE	219
33.1. TOOLS FOR MONITORING AND DIAGNOSING I/O AND FILE SYSTEM ISSUES	219
33.2. AVAILABLE TUNING OPTIONS FOR FORMATTING A FILE SYSTEM	221
33.3. AVAILABLE TUNING OPTIONS FOR MOUNTING A FILE SYSTEM	222
33.4. TYPES OF DISCARDING UNUSED BLOCKS	223
33.5. SOLID-STATE DISKS TUNING CONSIDERATIONS	223
33.6. GENERIC BLOCK DEVICE TUNING PARAMETERS	224
CHAPTER 34. CONFIGURING AN OPERATING SYSTEM TO OPTIMIZE ACCESS TO NETWORK RESOURCES	226
34.1. TOOLS FOR MONITORING AND DIAGNOSING PERFORMANCE ISSUES	226
34.2. BOTTLENECKS IN A PACKET RECEPTION	227
34.3. BUSY POLLING	228
34.3.1. Enabling busy polling	229
34.4. RECEIVE-SIDE SCALING	230
34.4.1. Viewing the interrupt request queues	230
34.5. RECEIVE PACKET STEERING	231
34.6. RECEIVE FLOW STEERING	232
34.6.1. Enabling Receive Flow Steering	232
34.7. ACCELERATED RFS	233
34.7.1. Enabling the ntuple filters	233
CHAPTER 35. CONFIGURING AN OPERATING SYSTEM TO OPTIMIZE MEMORY ACCESS	235
35.1. TOOLS FOR MONITORING AND DIAGNOSING SYSTEM MEMORY ISSUES	235
35.2. OVERVIEW OF A SYSTEM'S MEMORY	235
35.3. VIRTUAL MEMORY PARAMETERS	236
35.4. FILE SYSTEM PARAMETERS	239
35.5. KERNEL PARAMETERS	239

35.6. SETTING MEMORY-RELATED KERNEL PARAMETERS	240
CHAPTER 36. CONFIGURING HUGE PAGES	241
36.1. AVAILABLE HUGE PAGE FEATURES	241
36.2. PARAMETERS FOR RESERVING HUGETLB PAGES AT BOOT TIME	242
36.3. CONFIGURING HUGETLB AT BOOT TIME	242
36.4. PARAMETERS FOR RESERVING HUGETLB PAGES AT RUN TIME	244
36.5. CONFIGURING HUGETLB AT RUN TIME	245
36.6. ENABLING TRANSPARENT HUGE PAGES	246
36.7. DISABLING TRANSPARENT HUGE PAGES	246
36.8. IMPACT OF PAGE SIZE ON TRANSLATION LOOKASIDE BUFFER SIZE	247
CHAPTER 37. GETTING STARTED WITH SYSTEMTAP	248
37.1. THE PURPOSE OF SYSTEMTAP	248
37.2. INSTALLING SYSTEMTAP	248
37.3. PRIVILEGES TO RUN SYSTEMTAP	249
37.4. RUNNING SYSTEMTAP SCRIPTS	250
CHAPTER 38. CROSS-INSTRUMENTATION OF SYSTEMTAP	251
38.1. SYSTEMTAP CROSS-INSTRUMENTATION	251
38.2. INITIALIZING CROSS-INSTRUMENTATION OF SYSTEMTAP	252
CHAPTER 39. MONITORING NETWORK ACTIVITY WITH SYSTEMTAP	254
39.1. PROFILING NETWORK ACTIVITY WITH SYSTEMTAP	254
39.2. TRACING FUNCTIONS CALLED IN NETWORK SOCKET CODE WITH SYSTEMTAP	255
39.3. MONITORING NETWORK PACKET DROPS WITH SYSTEMTAP	256
CHAPTER 40. PROFILING KERNEL ACTIVITY WITH SYSTEMTAP	257
40.1. COUNTING FUNCTION CALLS WITH SYSTEMTAP	257
40.2. TRACING FUNCTION CALLS WITH SYSTEMTAP	258
40.3. DETERMINING TIME SPENT IN KERNEL AND USER SPACE WITH SYSTEMTAP	259
40.4. MONITORING POLLING APPLICATIONS WITH SYSTEMTAP	260
40.5. TRACKING MOST FREQUENTLY USED SYSTEM CALLS WITH SYSTEMTAP	261
40.6. TRACKING SYSTEM CALL VOLUME PER PROCESS WITH SYSTEMTAP	261
CHAPTER 41. MONITORING DISK AND I/O ACTIVITY WITH SYSTEMTAP	263
41.1. SUMMARIZING DISK READ/WRITE TRAFFIC WITH SYSTEMTAP	263
41.2. TRACKING I/O TIME FOR EACH FILE READ OR WRITE WITH SYSTEMTAP	264
41.3. TRACKING CUMULATIVE I/O WITH SYSTEMTAP	264
41.4. MONITORING I/O ACTIVITY ON A SPECIFIC DEVICE WITH SYSTEMTAP	265
41.5. MONITORING READS AND WRITES TO A FILE WITH SYSTEMTAP	266
CHAPTER 42. ANALYZING SYSTEM PERFORMANCE WITH BPF COMPILER COLLECTION	268
42.1. AN INTRODUCTION TO BCC	268
42.2. INSTALLING THE BCC-TOOLS PACKAGE	268
42.3. USING SELECTED BCC-TOOLS FOR PERFORMANCE ANALYSES	269
Using execsnoop to examine the system processes	269
Using opensnoop to track what files a command opens	270
Using biotop to examine the I/O operations on the disk	270
Using xfsslower to expose unexpectedly slow file system operations	272

MAKING OPEN SOURCE MORE INCLUSIVE

Red Hat is committed to replacing problematic language in our code, documentation, and web properties. We are beginning with these four terms: master, slave, blacklist, and whitelist. Because of the enormity of this endeavor, these changes will be implemented gradually over several upcoming releases. For more details, see [our CTO Chris Wright's message](#).

PROVIDING FEEDBACK ON RED HAT DOCUMENTATION

We appreciate your input on our documentation. Please let us know how we could make it better. To do so:

- For simple comments on specific passages:
 1. Make sure you are viewing the documentation in the *Multi-page HTML* format. In addition, ensure you see the **Feedback** button in the upper right corner of the document.
 2. Use your mouse cursor to highlight the part of text that you want to comment on.
 3. Click the **Add Feedback** pop-up that appears below the highlighted text.
 4. Follow the displayed instructions.
- For submitting more complex feedback, create a Bugzilla ticket:
 1. Go to the [Bugzilla](#) website.
 2. As the Component, use **Documentation**.
 3. Fill in the **Description** field with your suggestion for improvement. Include a link to the relevant part(s) of documentation.
 4. Click **Submit Bug**.

CHAPTER 1. OVERVIEW OF PERFORMANCE MONITORING OPTIONS

The following are some of the performance monitoring and configuration tools available in Red Hat Enterprise Linux 8:

- Performance Co-Pilot (**pcp**) is used for monitoring, visualizing, storing, and analyzing system-level performance measurements. It allows the monitoring and management of real-time data, and logging and retrieval of historical data.
- Red Hat Enterprise Linux 8 provides several tools that can be used from the command line to monitor a system outside run level **5**. The following are the built-in command line tools:
 - **top** is provided by the **procps-ng** package. It gives a dynamic view of the processes in a running system. It displays a variety of information, including a system summary and a list of tasks currently being managed by the Linux kernel.
 - **ps** is provided by the **procps-ng** package. It captures a snapshot of a select group of active processes. By default, the examined group is limited to processes that are owned by the current user and associated with the terminal where the **ps** command is executed.
 - Virtual memory statistics (**vmstat**) is provided by the **procps-ng** package. It provides instant reports of your system's processes, memory, paging, block input/output, interrupts, and CPU activity.
 - System activity reporter (**sar**) is provided by the **sysstat** package. It collects and reports information about system activity that has occurred so far on the current day.
- **perf** uses hardware performance counters and kernel trace-points to track the impact of other commands and applications on a system.
- **bcc-tools** is used for BPF Compiler Collection (BCC). It provides over 100 **eBPF** scripts that monitor kernel activities. For more information on each of this tool, see the man page describing how to use it and what functions it performs.
- **turbostat** is provided by the **kernel-tools** package. It reports on processor topology, frequency, idle power-state statistics, temperature, and power usage on the Intel 64 processors.
- **iostat** is provided by the **sysstat** package. It monitors and reports on system IO device loading to help administrators make decisions about how to balance IO load between physical disks.
- **irqbalance** distributes hardware interrupts across processors to improve system performance.
- **ss** prints statistical information about sockets, allowing administrators to assess device performance over time. Red Hat recommends using **ss** over **netstat** in Red Hat Enterprise Linux 8.
- **numastat** is provided by the **numactl** package. By default, **numastat** displays per-node NUMA hit and miss system statistics from the kernel memory allocator. Optimal performance is indicated by high **numa_hit** values and low **numa_miss** values.
- **numad** is an automatic NUMA affinity management daemon. It monitors NUMA topology and resource usage within a system that dynamically improves NUMA resource allocation, management, and therefore system performance.
- **SystemTap** monitors and analyzes operating system activities, especially the kernel activities.

- **valgrind** analyzes applications by running it on a synthetic CPU and instrumenting existing application code as it is executed. It then prints commentary that clearly identifies each process involved in application execution to a user-specified file, file descriptor, or network socket. It is also useful for finding memory leaks.
- **pqos** is provided by the the **intel-cmt-cat** package. It monitors and controls CPU cache and memory bandwidth on recent Intel processors.

Additional resources

- **pcp**, **top**, **ps**, **vmstat**, **sar**, **perf**, **iostat**, **irqbalance**, **ss**, **numastat**, **numad**, **valgrind**, and **pqos** man pages
- **/usr/share/doc/** directory
- [What exactly is the meaning of value "await" reported by iostat? Red Hat Knowledgebase article](#)
- [Monitoring performance with Performance Co-Pilot](#)

CHAPTER 2. GETTING STARTED WITH TUNED

As a system administrator, you can use the **Tuned** application to optimize the performance profile of your system for a variety of use cases.

2.1. THE PURPOSE OF TUNED

Tuned is a service that monitors your system and optimizes the performance under certain workloads. The core of **Tuned** are *profiles*, which tune your system for different use cases.

Tuned is distributed with a number of predefined profiles for use cases such as:

- High throughput
- Low latency
- Saving power

It is possible to modify the rules defined for each profile and customize how to tune a particular device. When you switch to another profile or deactivate **Tuned**, all changes made to the system settings by the previous profile revert back to their original state.

You can also configure **Tuned** to react to changes in device usage and adjusts settings to improve performance of active devices and reduce power consumption of inactive devices.

2.2. TUNED PROFILES

A detailed analysis of a system can be very time-consuming. **Tuned** provides a number of predefined profiles for typical use cases. You can also create, modify, and delete profiles.

The profiles provided with **Tuned** are divided into the following categories:

- Power-saving profiles
- Performance-boosting profiles

The performance-boosting profiles include profiles that focus on the following aspects:

- Low latency for storage and network
- High throughput for storage and network
- Virtual machine performance
- Virtualization host performance

Syntax of profile configuration

The **tuned.conf** file can contain one **[main]** section and other sections for configuring plug-in instances. However, all sections are optional.

Lines starting with the hash sign (**#**) are comments.

Additional resources

- **tuned.conf(5)** man page.

2.3. THE DEFAULT TUNED PROFILE

During the installation, the best profile for your system is selected automatically. Currently, the default profile is selected according to the following customizable rules:

Environment	Default profile	Goal
Compute nodes	throughput-performance	The best throughput performance
Virtual machines	virtual-guest	The best performance. If you are not interested in the best performance, you can change it to the balanced or powersave profile.
Other cases	balanced	Balanced performance and power consumption

Additional resources

- **tuned.conf(5)** man page.

2.4. MERGED TUNED PROFILES

As an experimental feature, it is possible to select more profiles at once. **Tuned** will try to merge them during the load.

If there are conflicts, the settings from the last specified profile takes precedence.

Example 2.1. Low power consumption in a virtual guest

The following example optimizes the system to run in a virtual machine for the best performance and concurrently tunes it for low power consumption, while the low power consumption is the priority:

```
# tuned-adm profile virtual-guest powersave
```

WARNING

Merging is done automatically without checking whether the resulting combination of parameters makes sense. Consequently, the feature might tune some parameters the opposite way, which might be counterproductive: for example, setting the disk for high throughput by using the **throughput-performance** profile and concurrently setting the disk spindown to the low value by the **spindown-disk** profile.

Additional resources

- **tuned.conf(5)** man page.

2.5. THE LOCATION OF TUNED PROFILES

TuneD stores profiles in the following directories:

/usr/lib/tuned/

Distribution-specific profiles are stored in the directory. Each profile has its own directory. The profile consists of the main configuration file called **tuned.conf**, and optionally other files, for example helper scripts.

/etc/tuned/

If you need to customize a profile, copy the profile directory into the directory, which is used for custom profiles. If there are two profiles of the same name, the custom profile located in **/etc/tuned/** is used.

Additional resources

- **tuned.conf(5)** man page.

2.6. TUNED PROFILES DISTRIBUTED WITH RHEL

The following is a list of profiles that are installed with **TuneD** on Red Hat Enterprise Linux.

NOTE

There might be more product-specific or third-party **TuneD** profiles available. Such profiles are usually provided by separate RPM packages.

balanced

The default power-saving profile. It is intended to be a compromise between performance and power consumption. It uses auto-scaling and auto-tuning whenever possible. The only drawback is the increased latency. In the current **TuneD** release, it enables the CPU, disk, audio, and video plugins, and activates the **conservative** CPU governor. The **radeon_powersave** option uses the **dpm-balanced** value if it is supported, otherwise it is set to **auto**.

It changes the **energy_performance_preference** attribute to the **normal** energy setting. It also changes the **scaling_governor** policy attribute to either the **conservative** or **powersave** CPU governor.

powersave

A profile for maximum power saving performance. It can throttle the performance in order to minimize the actual power consumption. In the current **TuneD** release it enables USB autosuspend, WiFi power saving, and Aggressive Link Power Management (ALPM) power savings for SATA host adapters. It also schedules multi-core power savings for systems with a low wakeup rate and activates the **ondemand** governor. It enables AC97 audio power saving or, depending on your system, HDA-Intel power savings with a 10 seconds timeout. If your system contains a supported Radeon graphics card with enabled KMS, the profile configures it to automatic power saving. On ASUS Eee PCs, a dynamic Super Hybrid Engine is enabled.

It changes the **energy_performance_preference** attribute to the **powersave** or **power** energy setting. It also changes the **scaling_governor** policy attribute to either the **ondemand** or **powersave** CPU governor.

NOTE

In certain cases, the **balanced** profile is more efficient compared to the **powersave** profile.

Consider there is a defined amount of work that needs to be done, for example a video file that needs to be transcoded. Your machine might consume less energy if the transcoding is done on the full power, because the task is finished quickly, the machine starts to idle, and it can automatically step-down to very efficient power save modes. On the other hand, if you transcode the file with a throttled machine, the machine consumes less power during the transcoding, but the process takes longer and the overall consumed energy can be higher.

That is why the **balanced** profile can be generally a better option.

throughput-performance

A server profile optimized for high throughput. It disables power savings mechanisms and enables **sysctl** settings that improve the throughput performance of the disk and network IO. CPU governor is set to **performance**.

It changes the **energy_performance_preference** and **scaling_governor** attribute to the **performance** profile.

accelerator-performance

The **accelerator-performance** profile contains the same tuning as the **throughput-performance** profile. Additionally, it locks the CPU to low C states so that the latency is less than 100us. This improves the performance of certain accelerators, such as GPUs.

latency-performance

A server profile optimized for low latency. It disables power savings mechanisms and enables **sysctl** settings that improve latency. CPU governor is set to **performance** and the CPU is locked to the low C states (by PM QoS).

It changes the **energy_performance_preference** and **scaling_governor** attribute to the **performance** profile.

network-latency

A profile for low latency network tuning. It is based on the **latency-performance** profile. It additionally disables transparent huge pages and NUMA balancing, and tunes several other network-related **sysctl** parameters.

It inherits the **latency-performance** profile which changes the **energy_performance_preference** and **scaling_governor** attribute to the **performance** profile.

hpc-compute

A profile optimized for high-performance computing. It is based on the **latency-performance** profile.

network-throughput

A profile for throughput network tuning. It is based on the **throughput-performance** profile. It additionally increases kernel network buffers.

It inherits either the **latency-performance** or **throughput-performance** profile, and changes the **energy_performance_preference** and **scaling_governor** attribute to the **performance** profile.

virtual-guest

A profile designed for Red Hat Enterprise Linux 8 virtual machines and VMWare guests based on the **throughput-performance** profile that, among other tasks, decreases virtual memory swappiness and increases disk readahead values. It does not disable disk barriers.

It inherits the **throughput-performance** profile and changes the **energy_performance_preference** and **scaling_governor** attribute to the **performance** profile.

virtual-host

A profile designed for virtual hosts based on the **throughput-performance** profile that, among other tasks, decreases virtual memory swappiness, increases disk readahead values, and enables a more aggressive value of dirty pages writeback.

It inherits the **throughput-performance** profile and changes the **energy_performance_preference** and **scaling_governor** attribute to the **performance** profile.

oracle

A profile optimized for Oracle databases loads based on **throughput-performance** profile. It additionally disables transparent huge pages and modifies other performance-related kernel parameters. This profile is provided by the **tuned-profiles-oracle** package.

desktop

A profile optimized for desktops, based on the **balanced** profile. It additionally enables scheduler autogroups for better response of interactive applications.

optimize-serial-console

A profile that tunes down I/O activity to the serial console by reducing the `printk` value. This should make the serial console more responsive. This profile is intended to be used as an overlay on other profiles. For example:

```
# tuned-adm profile throughput-performance optimize-serial-console
```

mssql

A profile provided for Microsoft SQL Server. It is based on the **throughput-performance** profile.

intel-sst

A profile optimized for systems with user-defined Intel Speed Select Technology configurations. This profile is intended to be used as an overlay on other profiles. For example:

```
# tuned-adm profile cpu-partitioning intel-sst
```

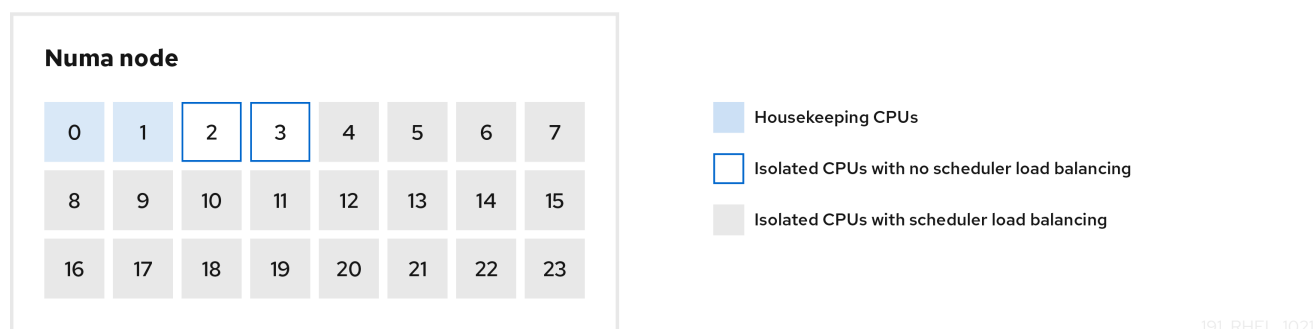

2.7. TUNED CPU-PARTITIONING PROFILE

For tuning Red Hat Enterprise Linux 8 for latency-sensitive workloads, Red Hat recommends to use the **cpu-partitioning** Tuned profile.

Prior to Red Hat Enterprise Linux 8, the low-latency Red Hat documentation described the numerous low-level steps needed to achieve low-latency tuning. In Red Hat Enterprise Linux 8, you can perform low-latency tuning more efficiently by using the **cpu-partitioning** Tuned profile. This profile is easily customizable according to the requirements for individual low-latency applications.

The following figure is an example to demonstrate how to use the **cpu-partitioning** profile. This example uses the `cpu` and `node` layout.

Figure 2.1. Figure cpu-partitioning

You can configure the cpu-partitioning profile in the `/etc/tuned/cpu-partitioning-variables.conf` file using the following configuration options:

Isolated cpus with load balancing

In the cpu-partitioning figure, the blocks numbered from 4 to 23, are the default isolated cpus. The kernel scheduler's process load balancing is enabled on these cpus. It is designed for low-latency processes with multiple threads that need the kernel scheduler load balancing.

You can configure the cpu-partitioning profile in the `/etc/tuned/cpu-partitioning-variables.conf` file using the **`isolated_cores=cpu-list`** option, which lists CPUs to isolate that will use the kernel scheduler load balancing.

The list of isolated CPUs is comma-separated or you can specify a range using a dash, such as **`3-5`**. This option is mandatory. Any CPU missing from this list is automatically considered a housekeeping CPU.

Isolated cpus without load balancing

In the cpu-partitioning figure, the blocks numbered 2 and 3, are the isolated cpus that do not provide any additional kernel scheduler process load balancing.

You can configure the cpu-partitioning profile in the `/etc/tuned/cpu-partitioning-variables.conf` file using the **`no_balance_cores=cpu-list`** option, which lists CPUs to isolate that will not use the kernel scheduler load balancing.

Specifying the **`no_balance_cores`** option is optional, however any cpus in this list must be a subset of the cpus listed in the **`isolated_cores`** list.

Application threads using these cpus need to be pinned individually to each cpu.

Housekeeping cpus

Any cpu not isolated in the `cpu-partitioning-variables.conf` file is automatically considered a housekeeping cpu. On the housekeeping cpus, all services, daemons, user processes, movable kernel threads, interrupt handlers, and kernel timers are permitted to execute.

Additional resources

- **`tuned-profiles-cpu-partitioning(7)`** man page

2.8. USING THE TUNED CPU-PARTITIONING PROFILE FOR LOW-LATENCY TUNING

This procedure describes how to tune a system for low-latency using the Tuned's **cpu-partitioning** profile. It uses the example of a low-latency application that can use **cpu-partitioning** and the CPU layout as mentioned in the [cpu-partitioning](#) figure.

The application in this case uses:

- One dedicated reader thread that reads data from the network will be pinned to CPU 2.
- A large number of threads that process this network data will be pinned to CPUs 4-23.
- A dedicated writer thread that writes the processed data to the network will be pinned to CPU 3.

Prerequisites

- You have installed the **cpu-partitioning** Tuned profile by using the **yum install tuned-profiles-cpu-partitioning** command as root.

Procedure

1. Edit **/etc/tuned/cpu-partitioning-variables.conf** file and add the following information:

```
# Isolated CPUs with the kernel's scheduler load balancing:
isolated_cores=2-23
# Isolated CPUs without the kernel's scheduler load balancing:
no_balance_cores=2,3
```

2. Set the **cpu-partitioning** Tuned profile:

```
# tuned-adm profile cpu-partitioning
```

3. Reboot

After rebooting, the system is tuned for low-latency, according to the isolation in the [cpu-partitioning](#) figure. The application can use taskset to pin the reader and writer threads to cpus 2 and 3, and the remaining application threads on cpus 4-23.

Additional resources

- **tuned-profiles-cpu-partitioning(7)** man page

2.9. CUSTOMIZING THE CPU-PARTITIONING TUNED PROFILE

You can extend the Tuned profile to make additional tuning changes.

For example, the **cpu-partitioning** profile sets the cpus to use **cstate=1**. In order to use the **cpu-partitioning** profile but to additionally change the CPU cstate from cstate1 to cstate0, the following procedure describes a new Tuned profile named *my_profile*, which inherits the **cpu-partitioning** profile and then sets C state-0.

Procedure

1. Create the **/etc/tuned/my_profile** directory:

```
# mkdir /etc/tuned/my_profile
```

2. Create a **tuned.conf** file in this directory, and add the following content:

```
# vi /etc/tuned/my_profile/tuned.conf
[main]
summary=Customized tuning on top of cpu-partitioning
include=cpu-partitioning
[cpu]
force_latency=cstate.id:0|1
```

3. Use the new profile:

```
# tuned-adm profile my_profile
```

NOTE

In the shared example, a reboot is not required. However, if the changes in the *my_profile* profile require a reboot to take effect, then reboot your machine.

Additional resources

- **tuned-profiles-cpu-partitioning(7)** man page

2.10. REAL-TIME TUNED PROFILES DISTRIBUTED WITH RHEL

Real-time profiles are intended for systems running the real-time kernel. Without a special kernel build, they do not configure the system to be real-time. On RHEL, the profiles are available from additional repositories.

The following real-time profiles are available:

realtime

Use on bare-metal real-time systems.

Provided by the **tuned-profiles-realtime** package, which is available from the RT or NFV repositories.

realtime-virtual-host

Use in a virtualization host configured for real-time.

Provided by the **tuned-profiles-nfv-host** package, which is available from the NFV repository.

realtime-virtual-guest

Use in a virtualization guest configured for real-time.

Provided by the **tuned-profiles-nfv-guest** package, which is available from the NFV repository.

2.11. STATIC AND DYNAMIC TUNING IN TUNED

This section explains the difference between the two categories of system tuning that **TuneD** applies: *static* and *dynamic*.

Static tuning

Mainly consists of the application of predefined **sysctl** and **sysfs** settings and one-shot activation of several configuration tools such as **ethtool**.

Dynamic tuning

Watches how various system components are used throughout the uptime of your system. **TuneD** adjusts system settings dynamically based on that monitoring information.

For example, the hard drive is used heavily during startup and login, but is barely used later when the user might mainly work with applications such as web browsers or email clients. Similarly, the CPU and network devices are used differently at different times. **TuneD** monitors the activity of these components and reacts to the changes in their use.

By default, dynamic tuning is disabled. To enable it, edit the `/etc/tuned/tuned-main.conf` file and change the **dynamic_tuning** option to **1**. **TuneD** then periodically analyzes system statistics and uses them to update your system tuning settings. To configure the time interval in seconds between these updates, use the **update_interval** option.

Currently implemented dynamic tuning algorithms try to balance the performance and powersave, and are therefore disabled in the performance profiles. Dynamic tuning for individual plug-ins can be enabled or disabled in the **TuneD** profiles.

Example 2.2. Static and dynamic tuning on a workstation

On a typical office workstation, the Ethernet network interface is inactive most of the time. Only a few emails go in and out or some web pages might be loaded.

For those kinds of loads, the network interface does not have to run at full speed all the time, as it does by default. **TuneD** has a monitoring and tuning plug-in for network devices that can detect this low activity and then automatically lower the speed of that interface, typically resulting in a lower power usage.

If the activity on the interface increases for a longer period of time, for example because a DVD image is being downloaded or an email with a large attachment is opened, **TuneD** detects this and sets the interface speed to maximum to offer the best performance while the activity level is high.

This principle is used for other plug-ins for CPU and disks as well.

2.12. TUNED NO-DAEMON MODE

You can run **TuneD** in **no-daemon** mode, which does not require any resident memory. In this mode, **TuneD** applies the settings and exits.

By default, **no-daemon** mode is disabled because a lot of **TuneD** functionality is missing in this mode, including:

- D-Bus support
- Hot-plug support
- Rollback support for settings

To enable **no-daemon** mode, include the following line in the `/etc/tuned/tuned-main.conf` file:

```
daemon = 0
```

2.13. INSTALLING AND ENABLING TUNED

This procedure installs and enables the **TuneD** application, installs **TuneD** profiles, and presets a default **TuneD** profile for your system.

Procedure

1. Install the **tuned** package:

```
# yum install tuned
```

2. Enable and start the **tuned** service:

```
# systemctl enable --now tuned
```

3. Optionally, install **TuneD** profiles for real-time systems:

```
# yum install tuned-profiles-realtime tuned-profiles-nfv
```

4. Verify that a **TuneD** profile is active and applied:

```
$ tuned-adm active
```

```
Current active profile: balanced
```

```
$ tuned-adm verify
```

```
Verification succeeded, current system settings match the preset profile.
See tuned log file ('/var/log/tuned/tuned.log') for details.
```

2.14. LISTING AVAILABLE TUNED PROFILES

This procedure lists all **TuneD** profiles that are currently available on your system.

Procedure

- To list all available **TuneD** profiles on your system, use:

```
$ tuned-adm list
```

```
Available profiles:
```

```
- balanced          - General non-specialized tuned profile
- desktop           - Optimize for the desktop use-case
- latency-performance - Optimize for deterministic performance at the cost of increased
power consumption
- network-latency   - Optimize for deterministic performance at the cost of increased power
consumption, focused on low latency network performance
- network-throughput - Optimize for streaming network throughput, generally only
necessary on older CPUs or 40G+ networks
- powersave        - Optimize for low power consumption
- throughput-performance - Broadly applicable tuning that provides excellent performance
across a variety of common server workloads
- virtual-guest     - Optimize for running inside a virtual guest
- virtual-host      - Optimize for running KVM guests
Current active profile: balanced
```

- To display only the currently active profile, use:

```
$ tuned-adm active

Current active profile: balanced
```

Additional resources

- **tuned-adm(8)** man page.

2.15. SETTING A TUNED PROFILE

This procedure activates a selected **TuneD** profile on your system.

Prerequisites

- The **tuned** service is running. See [Installing and Enabling TuneD](#) for details.

Procedure

1. Optionally, you can let **TuneD** recommend the most suitable profile for your system:

```
# tuned-adm recommend

balanced
```

2. Activate a profile:

```
# tuned-adm profile selected-profile
```

Alternatively, you can activate a combination of multiple profiles:

```
# tuned-adm profile profile1 profile2
```

Example 2.3. A virtual machine optimized for low power consumption

The following example optimizes the system to run in a virtual machine with the best performance and concurrently tunes it for low power consumption, while the low power consumption is the priority:

```
# tuned-adm profile virtual-guest powersave
```

3. View the current active **TuneD** profile on your system:

```
# tuned-adm active

Current active profile: selected-profile
```

4. Reboot the system:

```
# reboot
```

Verification steps

- Verify that the **TuneD** profile is active and applied:

```
$ tuned-adm verify
```

Verification succeeded, current system settings match the preset profile.
See tuned log file ('/var/log/tuned/tuned.log') for details.

Additional resources

- **tuned-adm(8)** man page

2.16. DISABLING TUNED

This procedure disables **TuneD** and resets all affected system settings to their original state before **TuneD** modified them.

Procedure

- To disable all tunings temporarily:

```
# tuned-adm off
```

The tunings are applied again after the **tuned** service restarts.

- Alternatively, to stop and disable the **tuned** service permanently:

```
# systemctl disable --now tuned
```

Additional resources

- **tuned-adm(8)** man page

CHAPTER 3. CUSTOMIZING TUNED PROFILES

You can create or modify **Tuned** profiles to optimize system performance for your intended use case.

Prerequisites

- Install and enable **Tuned** as described in [Installing and Enabling Tuned](#) for details.

3.1. TUNED PROFILES

A detailed analysis of a system can be very time-consuming. **Tuned** provides a number of predefined profiles for typical use cases. You can also create, modify, and delete profiles.

The profiles provided with **Tuned** are divided into the following categories:

- Power-saving profiles
- Performance-boosting profiles

The performance-boosting profiles include profiles that focus on the following aspects:

- Low latency for storage and network
- High throughput for storage and network
- Virtual machine performance
- Virtualization host performance

Syntax of profile configuration

The **tuned.conf** file can contain one **[main]** section and other sections for configuring plug-in instances. However, all sections are optional.

Lines starting with the hash sign (**#**) are comments.

Additional resources

- **tuned.conf(5)** man page.

3.2. THE DEFAULT TUNED PROFILE

During the installation, the best profile for your system is selected automatically. Currently, the default profile is selected according to the following customizable rules:

Environment	Default profile	Goal
Compute nodes	throughput-performance	The best throughput performance
Virtual machines	virtual-guest	The best performance. If you are not interested in the best performance, you can change it to the balanced or powersave profile.

Environment	Default profile	Goal
Other cases	balanced	Balanced performance and power consumption

Additional resources

- **tuned.conf(5)** man page.

3.3. MERGED TUNED PROFILES

As an experimental feature, it is possible to select more profiles at once. **TuneD** will try to merge them during the load.

If there are conflicts, the settings from the last specified profile takes precedence.

Example 3.1. Low power consumption in a virtual guest

The following example optimizes the system to run in a virtual machine for the best performance and concurrently tunes it for low power consumption, while the low power consumption is the priority:

```
# tuned-adm profile virtual-guest powersave
```

WARNING

Merging is done automatically without checking whether the resulting combination of parameters makes sense. Consequently, the feature might tune some parameters the opposite way, which might be counterproductive: for example, setting the disk for high throughput by using the **throughput-performance** profile and concurrently setting the disk spindown to the low value by the **spindown-disk** profile.

Additional resources

- **tuned.conf(5)** man page.

3.4. THE LOCATION OF TUNED PROFILES

TuneD stores profiles in the following directories:

/usr/lib/tuned/

Distribution-specific profiles are stored in the directory. Each profile has its own directory. The profile consists of the main configuration file called **tuned.conf**, and optionally other files, for example helper scripts.

/etc/tuned/

If you need to customize a profile, copy the profile directory into the directory, which is used for custom profiles. If there are two profiles of the same name, the custom profile located in **/etc/tuned/** is used.

Additional resources

- **tuned.conf(5)** man page.

3.5. INHERITANCE BETWEEN TUNED PROFILES

TuneD profiles can be based on other profiles and modify only certain aspects of their parent profile.

The **[main]** section of **TuneD** profiles recognizes the **include** option:

```
[main]
include=parent
```

All settings from the *parent* profile are loaded in this *child* profile. In the following sections, the *child* profile can override certain settings inherited from the *parent* profile or add new settings not present in the *parent* profile.

You can create your own *child* profile in the **/etc/tuned/** directory based on a pre-installed profile in **/usr/lib/tuned/** with only some parameters adjusted.

If the *parent* profile is updated, such as after a **TuneD** upgrade, the changes are reflected in the *child* profile.

Example 3.2. A power-saving profile based on balanced

The following is an example of a custom profile that extends the **balanced** profile and sets Aggressive Link Power Management (ALPM) for all devices to the maximum powersaving.

```
[main]
include=balanced

[scsi_host]
alpm=min_power
```

Additional resources

- **tuned.conf(5)** man page

3.6. STATIC AND DYNAMIC TUNING IN TUNED

This section explains the difference between the two categories of system tuning that **TuneD** applies: *static* and *dynamic*.

Static tuning

Mainly consists of the application of predefined **sysctl** and **sysfs** settings and one-shot activation of several configuration tools such as **ethtool**.

Dynamic tuning

Watches how various system components are used throughout the uptime of your system. **TuneD** adjusts system settings dynamically based on that monitoring information.

For example, the hard drive is used heavily during startup and login, but is barely used later when the user might mainly work with applications such as web browsers or email clients. Similarly, the CPU and network devices are used differently at different times. **TuneD** monitors the activity of these components and reacts to the changes in their use.

By default, dynamic tuning is disabled. To enable it, edit the `/etc/tuned/tuned-main.conf` file and change the **dynamic_tuning** option to **1**. **TuneD** then periodically analyzes system statistics and uses them to update your system tuning settings. To configure the time interval in seconds between these updates, use the **update_interval** option.

Currently implemented dynamic tuning algorithms try to balance the performance and powersave, and are therefore disabled in the performance profiles. Dynamic tuning for individual plug-ins can be enabled or disabled in the **TuneD** profiles.

Example 3.3. Static and dynamic tuning on a workstation

On a typical office workstation, the Ethernet network interface is inactive most of the time. Only a few emails go in and out or some web pages might be loaded.

For those kinds of loads, the network interface does not have to run at full speed all the time, as it does by default. **TuneD** has a monitoring and tuning plug-in for network devices that can detect this low activity and then automatically lower the speed of that interface, typically resulting in a lower power usage.

If the activity on the interface increases for a longer period of time, for example because a DVD image is being downloaded or an email with a large attachment is opened, **TuneD** detects this and sets the interface speed to maximum to offer the best performance while the activity level is high.

This principle is used for other plug-ins for CPU and disks as well.

3.7. TUNED PLUG-INS

Plug-ins are modules in **TuneD** profiles that **TuneD** uses to monitor or optimize different devices on the system.

TuneD uses two types of plug-ins:

Monitoring plug-ins

Monitoring plug-ins are used to get information from a running system. The output of the monitoring plug-ins can be used by tuning plug-ins for dynamic tuning.

Monitoring plug-ins are automatically instantiated whenever their metrics are needed by any of the enabled tuning plug-ins. If two tuning plug-ins require the same data, only one instance of the monitoring plug-in is created and the data is shared.

Tuning plug-ins

Each tuning plug-in tunes an individual subsystem and takes several parameters that are populated from the tuned profiles. Each subsystem can have multiple devices, such as multiple CPUs or network cards, that are handled by individual instances of the tuning plug-ins. Specific settings for individual devices are also supported.

Syntax for plug-ins in TuneD profiles

Sections describing plug-in instances are formatted in the following way:

```
[NAME]
type=TYPE
devices=DEVICES
```

NAME

is the name of the plug-in instance as it is used in the logs. It can be an arbitrary string.

TYPE

is the type of the tuning plug-in.

DEVICES

is the list of devices that this plug-in instance handles.

The **devices** line can contain a list, a wildcard (*), and negation (!). If there is no **devices** line, all devices present or later attached on the system of the *TYPE* are handled by the plug-in instance. This is same as using the **devices=*** option.

Example 3.4. Matching block devices with a plug-in

The following example matches all block devices starting with **sd**, such as **sda** or **sdb**, and does not disable barriers on them:

```
[data_disk]
type=disk
devices=sd*
disable_barriers=false
```

The following example matches all block devices except **sda1** and **sda2**:

```
[data_disk]
type=disk
devices=!sda1, !sda2
disable_barriers=false
```

If no instance of a plug-in is specified, the plug-in is not enabled.

If the plug-in supports more options, they can be also specified in the plug-in section. If the option is not specified and it was not previously specified in the included plug-in, the default value is used.

Short plug-in syntax

If you do not need custom names for the plug-in instance and there is only one definition of the instance in your configuration file, **TuneD** supports the following short syntax:

```
[TYPE]
devices=DEVICES
```

In this case, it is possible to omit the **type** line. The instance is then referred to with a name, same as the type. The previous example could be then rewritten into:

Example 3.5. Matching block devices using the short syntax

```
[disk]
devices=sdb*
disable_barriers=false
```

Conflicting plug-in definitions in a profile

If the same section is specified more than once using the **include** option, the settings are merged. If they cannot be merged due to a conflict, the last conflicting definition overrides the previous settings. If you do not know what was previously defined, you can use the **replace** Boolean option and set it to **true**. This causes all the previous definitions with the same name to be overwritten and the merge does not happen.

You can also disable the plug-in by specifying the **enabled=false** option. This has the same effect as if the instance was never defined. Disabling the plug-in is useful if you are redefining the previous definition from the **include** option and do not want the plug-in to be active in your custom profile.

NOTE

Tuned includes the ability to run any shell command as part of enabling or disabling a tuning profile. This enables you to extend **Tuned** profiles with functionality that has not been integrated into **Tuned** yet.

You can specify arbitrary shell commands using the **script** plug-in.

Additional resources

- **tuned.conf(5)** man page

3.8. AVAILABLE TUNED PLUG-INS

This section lists all monitoring and tuning plug-ins currently available in **Tuned**.

Monitoring plug-ins

Currently, the following monitoring plug-ins are implemented:

disk

Gets disk load (number of IO operations) per device and measurement interval.

net

Gets network load (number of transferred packets) per network card and measurement interval.

load

Gets CPU load per CPU and measurement interval.

Tuning plug-ins

Currently, the following tuning plug-ins are implemented. Only some of these plug-ins implement dynamic tuning. Options supported by plug-ins are also listed:

cpu

Sets the CPU governor to the value specified by the **governor** option and dynamically changes the Power Management Quality of Service (PM QoS) CPU Direct Memory Access (DMA) latency according to the CPU load.

If the CPU load is lower than the value specified by the **load_threshold** option, the latency is set to the value specified by the **latency_high** option, otherwise it is set to the value specified by **latency_low**.

You can also force the latency to a specific value and prevent it from dynamically changing further. To do so, set the **force_latency** option to the required latency value.

eeepc_she

Dynamically sets the front-side bus (FSB) speed according to the CPU load.

This feature can be found on some netbooks and is also known as the ASUS Super Hybrid Engine (SHE).

If the CPU load is lower or equal to the value specified by the **load_threshold_powersave** option, the plug-in sets the FSB speed to the value specified by the **she_powersave** option. If the CPU load is higher or equal to the value specified by the **load_threshold_normal** option, it sets the FSB speed to the value specified by the **she_normal** option.

Static tuning is not supported and the plug-in is transparently disabled if **Tuned** does not detect the hardware support for this feature.

net

Configures the Wake-on-LAN functionality to the values specified by the **wake_on_lan** option. It uses the same syntax as the **ethtool** utility. It also dynamically changes the interface speed according to the interface utilization.

sysctl

Sets various **sysctl** settings specified by the plug-in options.

The syntax is **name=value**, where *name* is the same as the name provided by the **sysctl** utility.

Use the **sysctl** plug-in if you need to change system settings that are not covered by other plug-ins available in **Tuned**. If the settings are covered by some specific plug-ins, prefer these plug-ins.

usb

Sets autosuspend timeout of USB devices to the value specified by the **autosuspend** parameter. The value **0** means that autosuspend is disabled.

vm

Enables or disables transparent huge pages depending on the value of the **transparent_hugepages** option.

Valid values of the **transparent_hugepages** option are:

- "always"
- "never"
- "madvise"

audio

Sets the autosuspend timeout for audio codecs to the value specified by the **timeout** option.

Currently, the **snd_hda_intel** and **snd_ac97_codec** codecs are supported. The value **0** means that the autosuspend is disabled. You can also enforce the controller reset by setting the Boolean option **reset_controller** to **true**.

disk

Sets the disk elevator to the value specified by the **elevator** option.

It also sets:

- APM to the value specified by the **apm** option
- Scheduler quantum to the value specified by the **scheduler_quantum** option
- Disk spindown timeout to the value specified by the **spindown** option
- Disk readahead to the value specified by the **readahead** parameter
- The current disk readahead to a value multiplied by the constant specified by the **readahead_multiply** option

In addition, this plug-in dynamically changes the advanced power management and spindown timeout setting for the drive according to the current drive utilization. The dynamic tuning can be controlled by the Boolean option **dynamic** and is enabled by default.

scsi_host

Tunes options for SCSI hosts.

It sets Aggressive Link Power Management (ALPM) to the value specified by the **alpm** option.

mounts

Enables or disables barriers for mounts according to the Boolean value of the **disable_barriers** option.

script

Executes an external script or binary when the profile is loaded or unloaded. You can choose an arbitrary executable.

IMPORTANT

The **script** plug-in is provided mainly for compatibility with earlier releases. Prefer other **TuneD** plug-ins if they cover the required functionality.

TuneD calls the executable with one of the following arguments:

- **start** when loading the profile
- **stop** when unloading the profile

You need to correctly implement the **stop** action in your executable and revert all settings that you changed during the **start** action. Otherwise, the roll-back step after changing your **TuneD** profile will not work.

Bash scripts can import the **/usr/lib/tuned/functions** Bash library and use the functions defined there. Use these functions only for functionality that is not natively provided by **TuneD**. If a function name starts with an underscore, such as **_wifi_set_power_level**, consider the function private and do not use it in your scripts, because it might change in the future.

Specify the path to the executable using the **script** parameter in the plug-in configuration.

Example 3.6. Running a Bash script from a profile

To run a Bash script named **script.sh** that is located in the profile directory, use:

```
[script]
script=${i:PROFILE_DIR}/script.sh
```

sysfs

Sets various **sysfs** settings specified by the plug-in options.

The syntax is **name=value**, where *name* is the **sysfs** path to use.

Use this plugin in case you need to change some settings that are not covered by other plug-ins. Prefer specific plug-ins if they cover the required settings.

video

Sets various powersave levels on video cards. Currently, only the Radeon cards are supported.

The powersave level can be specified by using the **radeon_powersave** option. Supported values are:

- **default**
- **auto**
- **low**
- **mid**
- **high**
- **dynpm**
- **dpm-battery**
- **dpm-balanced**
- **dpm-performance**

For details, see www.x.org. Note that this plug-in is experimental and the option might change in future releases.

bootloader

Adds options to the kernel command line. This plug-in supports only the GRUB 2 boot loader. Customized non-standard location of the GRUB 2 configuration file can be specified by the **grub2_cfg_file** option.

The kernel options are added to the current GRUB configuration and its templates. The system needs to be rebooted for the kernel options to take effect.

Switching to another profile or manually stopping the **tuned** service removes the additional options. If you shut down or reboot the system, the kernel options persist in the **grub.cfg** file.

The kernel options can be specified by the following syntax:

```
cmdline=arg1 arg2 ... argN
```

Example 3.7. Modifying the kernel command line

For example, to add the **quiet** kernel option to a **Tuned** profile, include the following lines in the **tuned.conf** file:

```
[bootloader]
cmdline=quiet
```

The following is an example of a custom profile that adds the **isolcpus=2** option to the kernel command line:

```
[bootloader]
cmdline=isolcpus=2
```

3.9. VARIABLES IN TUNED PROFILES

Variables expand at run time when a **Tuned** profile is activated.

Using **Tuned** variables reduces the amount of necessary typing in **Tuned** profiles.

There are no predefined variables in **Tuned** profiles. You can define your own variables by creating the **[variables]** section in a profile and using the following syntax:

```
[variables]

variable_name=value
```

To expand the value of a variable in a profile, use the following syntax:

```
${variable_name}
```

Example 3.8. Isolating CPU cores using variables

In the following example, the **\${isolated_cores}** variable expands to **1,2**; hence the kernel boots with the **isolcpus=1,2** option:

```
[variables]
isolated_cores=1,2

[bootloader]
cmdline=isolcpus=${isolated_cores}
```

The variables can be specified in a separate file. For example, you can add the following lines to **tuned.conf**:

```
[variables]
include=/etc/tuned/my-variables.conf

[bootloader]
cmdline=isolcpus=${isolated_cores}
```

If you add the **isolated_cores=1,2** option to the **/etc/tuned/my-variables.conf** file, the kernel boots with the **isolcpus=1,2** option.

Additional resources

- **tuned.conf(5)** man page

3.10. BUILT-IN FUNCTIONS IN TUNED PROFILES

Built-in functions expand at run time when a **TuneD** profile is activated.

You can:

- Use various built-in functions together with **TuneD** variables
- Create custom functions in Python and add them to **TuneD** in the form of plug-ins

To call a function, use the following syntax:

```
${f:function_name:argument_1:argument_2}
```

To expand the directory path where the profile and the **tuned.conf** file are located, use the **PROFILE_DIR** function, which requires special syntax:

```
${i:PROFILE_DIR}
```

Example 3.9. Isolating CPU cores using variables and built-in functions

In the following example, the **\${non_isolated_cores}** variable expands to **0,3-5**, and the **cpulist_invert** built-in function is called with the **0,3-5** argument:

```
[variables]
non_isolated_cores=0,3-5

[bootloader]
cmdline=isolcpus=${f:cpulist_invert:${non_isolated_cores}}
```

The **cpulist_invert** function inverts the list of CPUs. For a 6-CPU machine, the inversion is **1,2**, and the kernel boots with the **isolcpus=1,2** command-line option.

Additional resources

- **tuned.conf(5)** man page

3.11. BUILT-IN FUNCTIONS AVAILABLE IN TUNED PROFILES

The following built-in functions are available in all **TuneD** profiles:

PROFILE_DIR

Returns the directory path where the profile and the **tuned.conf** file are located.

exec

Executes a process and returns its output.

assertion

Compares two arguments. If they *do not match*, the function logs text from the first argument and aborts profile loading.

assertion_non_equal

Compares two arguments. If they *match*, the function logs text from the first argument and aborts profile loading.

kb2s

Converts kilobytes to disk sectors.

s2kb

Converts disk sectors to kilobytes.

strip

Creates a string from all passed arguments and deletes both leading and trailing white space.

virt_check

Checks whether **TuneD** is running inside a virtual machine (VM) or on bare metal:

- Inside a VM, the function returns the first argument.
- On bare metal, the function returns the second argument, even in case of an error.

cpulist_invert

Inverts a list of CPUs to make its complement. For example, on a system with 4 CPUs, numbered from 0 to 3, the inversion of the list **0,2,3** is **1**.

cpulist2hex

Converts a CPU list to a hexadecimal CPU mask.

cpulist2hex_invert

Converts a CPU list to a hexadecimal CPU mask and inverts it.

hex2cpulist

Converts a hexadecimal CPU mask to a CPU list.

cpulist_online

Checks whether the CPUs from the list are online. Returns the list containing only online CPUs.

cpulist_present

Checks whether the CPUs from the list are present. Returns the list containing only present CPUs.

cpulist_unpack

Unpacks a CPU list in the form of **1-3,4** to **1,2,3,4**.

cpulist_pack

Packs a CPU list in the form of **1,2,3,5** to **1-3,5**.

3.12. CREATING NEW TUNED PROFILES

This procedure creates a new **TuneD** profile with custom performance rules.

Prerequisites

- The **tuned** service is running. See [Installing and Enabling TuneD](#) for details.

Procedure

1. In the **/etc/tuned/** directory, create a new directory named the same as the profile that you want to create:

```
# mkdir /etc/tuned/my-profile
```

2. In the new directory, create a file named **tuned.conf**. Add a **[main]** section and plug-in definitions in it, according to your requirements.

For example, see the configuration of the **balanced** profile:

```
[main]
summary=General non-specialized tuned profile

[cpu]
governor=conservative
energy_perf_bias=normal

[audio]
timeout=10

[video]
radeon_powersave=dpm-balanced, auto

[scsi_host]
alpm=medium_power
```

3. To activate the profile, use:

```
# tuned-adm profile my-profile
```

4. Verify that the **TuneD** profile is active and the system settings are applied:

```
$ tuned-adm active

Current active profile: my-profile

$ tuned-adm verify

Verification succeeded, current system settings match the preset profile.
See tuned log file ('/var/log/tuned/tuned.log') for details.
```

Additional resources

- **tuned.conf(5)** man page

3.13. MODIFYING EXISTING TUNED PROFILES

This procedure creates a modified child profile based on an existing **TuneD** profile.

Prerequisites

- The **tuned** service is running. See [Installing and Enabling TuneD](#) for details.

Procedure

1. In the **/etc/tuned/** directory, create a new directory named the same as the profile that you want to create:

```
# mkdir /etc/tuned/modified-profile
```

2. In the new directory, create a file named **tuned.conf**, and set the **[main]** section as follows:

```
[main]
include=parent-profile
```

Replace *parent-profile* with the name of the profile you are modifying.

3. Include your profile modifications.

Example 3.10. Lowering swappiness in the throughput-performance profile

To use the settings from the **throughput-performance** profile and change the value of **vm.swappiness** to 5, instead of the default 10, use:

```
[main]
include=throughput-performance

[sysctl]
vm.swappiness=5
```

4. To activate the profile, use:

```
# tuned-adm profile modified-profile
```

5. Verify that the **TuneD** profile is active and the system settings are applied:

```
$ tuned-adm active
```

```
Current active profile: my-profile
```

```
$ tuned-adm verify
```

```
Verification succeeded, current system settings match the preset profile.
See tuned log file ('/var/log/tuned/tuned.log') for details.
```

Additional resources

- **tuned.conf(5)** man page

3.14. SETTING THE DISK SCHEDULER USING TUNED

This procedure creates and enables a **TuneD** profile that sets a given disk scheduler for selected block devices. The setting persists across system reboots.

In the following commands and configuration, replace:

- *device* with the name of the block device, for example **sdf**
- *selected-scheduler* with the disk scheduler that you want to set for the device, for example **bfq**

Prerequisites

- The **tuned** service is installed and enabled. For details, see [Installing and enabling Tuned](#).

Procedure

1. Optional: Select an existing **Tuned** profile on which your profile will be based. For a list of available profiles, see [Tuned profiles distributed with RHEL](#).
To see which profile is currently active, use:

```
$ tuned-adm active
```

2. Create a new directory to hold your **Tuned** profile:

```
# mkdir /etc/tuned/my-profile
```

3. Find the system unique identifier of the selected block device:

```
$ udevadm info --query=property --name=/dev/device | grep -E '(WWN|SERIAL)'

ID_WWN=0x5002538d00000000_
ID_SERIAL=Generic-SD_MMC_20120501030900000-0:0
ID_SERIAL_SHORT=20120501030900000
```

NOTE

The command in this example will return all values identified as a World Wide Name (WWN) or serial number associated with the specified block device. Although it is preferred to use a WWN, the WWN is not always available for a given device and any values returned by the example command are acceptable to use as the *device system unique ID*.

4. Create the **/etc/tuned/my-profile/tuned.conf** configuration file. In the file, set the following options:

- a. Optional: Include an existing profile:

```
[main]
include=existing-profile
```

- b. Set the selected disk scheduler for the device that matches the WWN identifier:

```
[disk]
devices_udev_regex=IDNAME=device system unique id
elevator=selected-scheduler
```

Here:

- Replace *IDNAME* with the name of the identifier being used (for example, **ID_WWN**).

- Replace *device system unique id* with the value of the chosen identifier (for example, **0x5002538d00000000**).
To match multiple devices in the **devices_udev_regex** option, enclose the identifiers in parentheses and separate them with vertical bars:

```
devices_udev_regex=(ID_WWN=0x5002538d00000000)|  
(ID_WWN=0x1234567800000000)
```

5. Enable your profile:

```
# tuned-adm profile my-profile
```

Verification steps

- Verify that the TuneD profile is active and applied:

```
$ tuned-adm active
```

```
Current active profile: my-profile
```

```
$ tuned-adm verify
```

```
Verification succeeded, current system settings match the preset profile.  
See tuned log file ('/var/log/tuned/tuned.log') for details.
```

Additional resources

- [Customizing TuneD profiles](#)

CHAPTER 4. REVIEWING A SYSTEM USING TUNA INTERFACE

Use the **tuna** tool to adjust scheduler tunables, tune thread priority, IRQ handlers, and isolate CPU cores and sockets. Tuna reduces the complexity of performing tuning tasks.

The **tuna** tool performs the following operations:

- Lists the CPUs on a system
- Lists the interrupt requests (IRQs) currently running on a system
- Changes policy and priority information on threads
- Displays the current policies and priorities of a system

4.1. INSTALLING TUNA TOOL

The **tuna** tool is designed to be used on a running system. This allows application-specific measurement tools to see and analyze system performance immediately after changes have been made.

This procedure describes how to install the **tuna** tool.

Procedure

- Install the **tuna** tool:

```
# yum install tuna
```

Verification steps

- View the available **tuna** CLI options:

```
# tuna -h
```

Additional resources

- **tuna(8)** man page

4.2. VIEWING THE SYSTEM STATUS USING TUNA TOOL

This procedure describes how to view the system status using the **tuna** command-line interface (CLI) tool.

Prerequisites

- The tuna tool is installed. For more information, see [Installing tuna tool](#).

Procedure

- To view the current policies and priorities:

```
# tuna --show_threads  
thread
```

```

pid  SCHED_ rtpri affinity      cmd
1    OTHER  0      0,1      init
2    FIFO   99      0      migration/0
3    OTHER  0      0      ksoftirqd/0
4    FIFO   99      0      watchdog/0

```

- To view a specific thread corresponding to a PID or matching a command name:

```
# tuna --threads=pid_or_cmd_list --show_threads
```

The *pid_or_cmd_list* argument is a list of comma-separated PIDs or command-name patterns.

- To tune CPUs using the **tuna** CLI, see [Tuning CPUs using tuna tool](#).
- To tune the IRQs using the **tuna** tool, see [Tuning IRQs using tuna tool](#).
- To save the changed configuration:

```
# tuna --save=filename
```

This command saves only currently running kernel threads. Processes that are not running are not saved.

Additional resources

- **tuna(8)** man page

4.3. TUNING CPUS USING TUNA TOOL

The **tuna** tool commands can target individual CPUs.

Using the tuna tool, you can:

Isolate CPUs

All tasks running on the specified CPU move to the next available CPU. Isolating a CPU makes it unavailable by removing it from the affinity mask of all threads.

Include CPUs

Allows tasks to run on the specified CPU

Restore CPUs

Restores the specified CPU to its previous configuration.

This procedure describes how to tune CPUs using the **tuna** CLI.

Prerequisites

- The tuna tool is installed. For more information, see [Installing tuna tool](#).

Procedure

- To specify the list of CPUs to be affected by a command:

```
# tuna --cpus=cpu_list [command]
```

The *cpu_list* argument is a list of comma-separated CPU numbers. For example, **--cpus=0,2**. CPU lists can also be specified in a range, for example **--cpus="1-3"**, which would select CPUs 1, 2, and 3.

To add a specific CPU to the current *cpu_list*, for example, use **--cpus=+0**.

Replace *[command]* with, for example, **--isolate**.

- To isolate a CPU:

```
# tuna --cpus=cpu_list --isolate
```

- To include a CPU:

```
# tuna --cpus=cpu_list --include
```

- To use a system with four or more processors, display how to make all the ssh threads run on CPU 0 and 1, and all the **http** threads on CPU 2 and 3:

```
# tuna --cpus=0,1 --threads=ssh\* \
--move --cpus=2,3 --threads=http\* --move
```

This command performs the following operations sequentially:

1. Selects CPUs 0 and 1.
2. Selects all threads that begin with **ssh**.
3. Moves the selected threads to the selected CPUs. Tuna sets the affinity mask of threads starting with **ssh** to the appropriate CPUs. The CPUs can be expressed numerically as 0 and 1, in hex mask as 0x3, or in binary as 11.
4. Resets the CPU list to 2 and 3.
5. Selects all threads that begin with **http**.
6. Moves the selected threads to the specified CPUs. Tuna sets the affinity mask of threads starting with **http** to the specified CPUs. The CPUs can be expressed numerically as 2 and 3, in hex mask as 0xC, or in binary as 1100.

Verification steps

- Display the current configuration and verify that the changes were performed as expected:

```
# tuna --threads=gnome-sc\* --show_threads \
--cpus=0 --move --show_threads --cpus=1 \
--move --show_threads --cpus=+0 --move --show_threads
```

	thread	ctxt_switches				
pid	SCHED_	rtpri	affinity	voluntary	nonvoluntary	cmd
3861	OTHER	0	0,1	33997	58	gnome-screensav

	thread	ctxt_switches				
pid	SCHED_	rtpri	affinity	voluntary	nonvoluntary	cmd
3861	OTHER	0	0	33997	58	gnome-screensav

```

pid SCHED_ rtpri affinity voluntary nonvoluntary      cmd
3861  OTHER    0      1  33997      58 gnome-screensav
      thread    ctxt_switches
pid SCHED_ rtpri affinity voluntary nonvoluntary      cmd
3861  OTHER    0    0,1  33997      58 gnome-screensav

```

This command performs the following operations sequentially:

1. Selects all threads that begin with the **gnome-sc** threads.
2. Displays the selected threads to enable the user to verify their affinity mask and RT priority.
3. Selects CPU 0.
4. Moves the **gnome-sc** threads to the specified CPU, CPU 0.
5. Shows the result of the move.
6. Resets the CPU list to CPU 1.
7. Moves the **gnome-sc** threads to the specified CPU, CPU 1.
8. Displays the result of the move.
9. Adds CPU 0 to the CPU list.
10. Moves the **gnome-sc** threads to the specified CPUs, CPUs 0 and 1.
11. Displays the result of the move.

Additional resources

- `/proc/cpuinfo` file
- **tuna(8)** man page

4.4. TUNING IRQS USING TUNA TOOL

The `/proc/interrupts` file records the number of interrupts per IRQ, the type of interrupt, and the name of the device that is located at that IRQ.

This procedure describes how to tune the IRQs using the **tuna** tool.

Prerequisites

- The tuna tool is installed. For more information, see [Installing tuna tool](#).

Procedure

- To view the current IRQs and their affinity:

```

# tuna --show_irqs
# users      affinity
0 timer      0
1 i8042      0
7 parport0   0

```

- To specify the list of IRQs to be affected by a command:

```
# tuna --irqs=irq_list [command]
```

The *irq_list* argument is a list of comma-separated IRQ numbers or user-name patterns.

Replace [*command*] with, for example, **--spread**.

- To move an interrupt to a specified CPU:

```
# tuna --irqs=128 --show_irqs
# users      affinity
128 iwlwifi   0,1,2,3

# tuna --irqs=128 --cpus=3 --move
```

Replace *128* with the *irq_list* argument and *3* with the *cpu_list* argument.

The *cpu_list* argument is a list of comma-separated CPU numbers, for example, **--cpus=0,2**. For more information, see [Tuning CPUs using tuna tool](#).

Verification steps

- Compare the state of the selected IRQs before and after moving any interrupt to a specified CPU:

```
# tuna --irqs=128 --show_irqs
# users      affinity
128 iwlwifi   3
```

Additional resources

- **/procs/interrupts** file
- **tuna(8)** man page

CHAPTER 5. MONITORING PERFORMANCE USING RHEL SYSTEM ROLES

As a system administrator, you can use the metrics RHEL System Role with any Ansible Automation Platform control node to monitor the performance of a system.

5.1. INTRODUCTION TO RHEL SYSTEM ROLES

RHEL System Roles is a collection of Ansible roles and modules. RHEL System Roles provide a configuration interface to remotely manage multiple RHEL systems. The interface enables managing system configurations across multiple versions of RHEL, as well as adopting new major releases.

On Red Hat Enterprise Linux 8, the interface currently consists of the following roles:

- `kdump`
- `network`
- `selinux`
- `storage`
- `certificate`
- `kernel_settings`
- `logging`
- `metrics`
- `nbde_client` and `nbde_server`
- `timesync`
- `tlog`

All these roles are provided by the **rhel-system-roles** package available in the **AppStream** repository.

Additional resources

- [Red Hat Enterprise Linux \(RHEL\) System Roles](#)
- `/usr/share/doc/rhel-system-roles` documentation ^[1]

5.2. RHEL SYSTEM ROLES TERMINOLOGY

You can find the following terms across this documentation:

System Roles terminology

Ansible playbook

Playbooks are Ansible's configuration, deployment, and orchestration language. They can describe a policy you want your remote systems to enforce, or a set of steps in a general IT process.

Control node

Any machine with Ansible installed. You can run commands and playbooks, invoking `/usr/bin/ansible` or `/usr/bin/ansible-playbook`, from any control node. You can use any computer that has Python installed on it as a control node – laptops, shared desktops, and servers can all run Ansible. However, you cannot use a Windows machine as a control node. You can have multiple control nodes.

Inventory

A list of managed nodes. An inventory file is also sometimes called a “hostfile”. Your inventory can specify information like IP address for each managed node. An inventory can also organize managed nodes, creating and nesting groups for easier scaling. To learn more about inventory, see the [Working with Inventory](#) section.

Managed nodes

The network devices, servers, or both that you manage with Ansible. Managed nodes are also sometimes called “hosts”. Ansible is not installed on managed nodes.

5.3. INSTALLING RHEL SYSTEM ROLES IN YOUR SYSTEM

To use the RHEL System Roles, install the required packages in your system.

Prerequisites

- You have a Red Hat Ansible Engine Subscription. See the procedure [How do I Download and Install Red Hat Ansible Engine?](#)
- You have Ansible packages installed in the system you want to use as a control node:

Procedure

1. Install the **rhel-system-roles** package on the system that you want to use as a control node:

```
# yum install rhel-system-roles
```

If you do not have a Red Hat Ansible Engine Subscription, you can use a limited supported version of Red Hat Ansible Engine provided with your Red Hat Enterprise Linux subscription. In this case, follow these steps:

- a. Enable the RHEL Ansible Engine repository:

```
# subscription-manager refresh
# subscription-manager repos --enable ansible-2-for-rhel-8-x86_64-rpms
```

- b. Install Ansible Engine:

```
# yum install ansible
```

As a result, you are able to create an Ansible playbook.

Additional resources

- The [Red Hat Enterprise Linux \(RHEL\) System Roles](#)
- The **ansible-playbook** man page.

5.4. APPLYING A ROLE

The following procedure describes how to apply a particular role.

Prerequisites

- Ensure that the **rhel-system-roles** package is installed on the system that you want to use as a control node:

```
# yum install rhel-system-roles
```

- You need the **ansible** package to run playbooks that use RHEL System Roles. Ensure that the Ansible Engine repository is enabled, and the **ansible** package is installed on the system that you want to use as a control node.
 - If you do not have a Red Hat Ansible Engine Subscription, you can use a limited supported version of Red Hat Ansible Engine provided with your Red Hat Enterprise Linux subscription. In this case, follow these steps:

1. Enable the RHEL Ansible Engine repository:

```
# subscription-manager refresh
# subscription-manager repos --enable ansible-2-for-rhel-8-x86_64-rpms
```

2. Install Ansible Engine:

```
# yum install ansible
```

- If you have a Red Hat Ansible Engine Subscription, follow the procedure described in [How do I Download and Install Red Hat Ansible Engine?](#).
- Ensure that you are able to create an Ansible inventory. Inventories represent the hosts, host groups, and some of the configuration parameters used by the Ansible playbooks.

Playbooks are typically human-readable, and are defined in **ini**, **yaml**, **json**, and other file formats.

- Ensure that you are able to create an Ansible playbook. Playbooks represent Ansible's configuration, deployment, and orchestration language. By using playbooks, you can declare and manage configurations of remote machines, deploy multiple remote machines or orchestrate steps of any manual ordered process.

A playbook is a list of one or more **plays**. Every **play** can include Ansible variables, tasks, or roles.

Playbooks are human-readable, and are defined in the **yaml** format.

Procedure

1. Create the required Ansible inventory containing the hosts and groups that you want to manage. Here is an example using a file called **inventory.ini** of a group of hosts called **webservers**:

```
[webservers]
host1
```

```
host2
host3
```

2. Create an Ansible playbook including the required role. The following example shows how to use roles through the **roles:** option for a playbook:

The following example shows how to use roles through the **roles:** option for a given **play:**

```
---
- hosts: webservers
  roles:
    - rhel-system-roles.network
    - rhel-system-roles.timesync
```

NOTE

Every role includes a README file, which documents how to use the role and supported parameter values. You can also find an example playbook for a particular role under the documentation directory of the role. Such documentation directory is provided by default with the **rhel-system-roles** package, and can be found in the following location:

```
/usr/share/doc/rhel-system-roles/SUBSYSTEM/
```

Replace *SUBSYSTEM* with the name of the required role, such as **selinux**, **kdump**, **network**, **timesync**, or **storage**.

3. To execute the playbook on specific hosts, you must perform one of the following:
 - Edit the playbook to use **hosts: host1[,host2,...]**, or **hosts: all**, and execute the command:

```
# ansible-playbook name.of.the.playbook
```

- Edit the inventory to ensure that the hosts you want to use are defined in a group, and execute the command:

```
# ansible-playbook -i name.of.the.inventory name.of.the.playbook
```

- Specify all hosts when executing the **ansible-playbook** command:

```
# ansible-playbook -i host1,host2,... name.of.the.playbook
```

IMPORTANT

Be aware that the **-i** flag specifies the inventory of all hosts that are available. If you have multiple targeted hosts, but want to select a host against which you want to run the playbook, you can add a variable in the playbook to be able to select a host. For example:

```
Ansible Playbook | example-playbook.yml:

- hosts: "{{ target_host }}"
  roles:
    - rhel-system-roles.network
    - rhel-system-roles.timesync
```

Playbook execution command:

```
# ansible-playbook -i host1,..hostn -e target_host=host5 example-
playbook.yml
```

5.5. INTRODUCTION TO THE METRICS SYSTEM ROLE

RHEL System Roles is a collection of Ansible roles and modules that provide a consistent configuration interface to remotely manage multiple RHEL systems. The metrics System Role configures performance analysis services for the local system and, optionally, includes a list of remote systems to be monitored by the local system. The metrics System Role enables you to use **pcp** to monitor your systems performance without having to configure **pcp** separately, as the set-up and deployment of **pcp** is handled by the playbook.

Table 5.1. Metrics system role variables

Role variable	Description	Example usage
metrics_monitored_hosts	List of remote hosts to be analyzed by the target host. These hosts will have metrics recorded on the target host, so ensure enough disk space exists below /var/log for each host.	metrics_monitored_hosts: [" webserver.example.com ", " database.example.com "]

Role variable	Description	Example usage
<code>metrics_retention_days</code>	Configures the number of days for performance data retention before deletion.	<code>metrics_retention_days: 14</code>
<code>metrics_graph_service</code>	A boolean flag that enables the host to be set up with services for performance data visualization via pcp and grafana . Set to false by default.	<code>metrics_graph_service: no</code>
<code>metrics_query_service</code>	A boolean flag that enables the host to be set up with time series query services for querying recorded pcp metrics via redis . Set to false by default.	<code>metrics_query_service: no</code>
<code>metrics_provider</code>	Specifies which metrics collector to use to provide metrics. Currently, pcp is the only supported metrics provider.	<code>metrics_provider: "pcp"</code>

NOTE

For details about the parameters used in **metrics_connections** and additional information about the metrics System Role, see the `/usr/share/ansible/roles/rhel-system-roles.metrics/README.md` file.

5.6. USING THE METRICS SYSTEM ROLE TO MONITOR YOUR LOCAL SYSTEM WITH VISUALIZATION

This procedure describes how to use the metrics RHEL System Role to monitor your local system while simultaneously provisioning data visualization via **Grafana**.

Prerequisites

- You have Red Hat Ansible Engine installed on the machine you want to monitor.
- You have the **rhel-system-roles** package installed on the machine you want to monitor.

Procedure

1. Configure **localhost** in the the `/etc/ansible/hosts` Ansible inventory by adding the following content to the inventory:

```
localhost ansible_connection=local
```

2. Create an Ansible playbook with the following content:

```
---
```

```
- hosts: localhost
  vars:
    metrics_graph_service: yes
  roles:
    - rhel-system-roles.metrics
```

3. Run the Ansible playbook:

```
# ansible-playbook name_of_your_playbook.yml
```

NOTE

Since the **metrics_graph_service** boolean is set to value="yes", **Grafana** is automatically installed and provisioned with **pcp** added as a data source.

4. To view visualization of the metrics being collected on your machine, access the **grafana** web interface as described in [Accessing the Grafana web UI](#).

5.7. USING THE METRICS SYSTEM ROLE TO SETUP A FLEET OF INDIVIDUAL SYSTEMS TO MONITOR THEMSELVES

This procedure describes how to use the metrics System Role to set up a fleet of machines to monitor themselves.

Prerequisites

- You have Red Hat Ansible Engine installed on the machine you want to use to run the playbook.
- You have the **rhel-system-roles** package installed on the machine you want to use to run the playbook.
- You have the SSH connection established.

Procedure

1. Add the name or IP of the machines you wish to monitor via the playbook to the **/etc/ansible/hosts** Ansible inventory file under an identifying group name enclosed in brackets:

```
[remotes]
webserver.example.com
database.example.com
```

2. Create an Ansible playbook with the following content:

```
---
- hosts: remotes
  vars:
    metrics_retention_days: 0
  roles:
    - rhel-system-roles.metrics
```

3. Run the Ansible playbook:

■

```
# ansible-playbook name_of_your_playbook.yml -k
```

Where the **-k** prompt for password to connect to remote system.

5.8. USING THE METRICS SYSTEM ROLE TO MONITOR A FLEET OF MACHINES CENTRALLY VIA YOUR LOCAL MACHINE

This procedure describes how to use the metrics System Role to set up your local machine to centrally monitor a fleet of machines while also provisioning visualization of the data via **grafana** and querying of the data via **redis**.

Prerequisites

- You have Red Hat Ansible Engine installed on the machine you want to use to run the playbook.
- You have the **rhel-system-roles** package installed on the machine you want to use to run the playbook.

Procedure

1. Create an Ansible playbook with the following content:

```
---
- hosts: localhost
  vars:
    metrics_graph_service: yes
    metrics_query_service: yes
    metrics_retention_days: 10
    metrics_monitored_hosts: ["database.example.com", "webserver.example.com"]
  roles:
    - rhel-system-roles.metrics
```

2. Run the Ansible playbook:

```
# ansible-playbook name_of_your_playbook.yml
```

NOTE

Since the **metrics_graph_service** and **metrics_query_service** booleans are set to value="yes", **grafana** is automatically installed and provisioned with **pcp** added as a data source with the **pcp** data recording indexed into **redis**, allowing the **pcp** querying language to be used for complex querying of the data.

3. To view graphical representation of the metrics being collected centrally by your machine and to query the data, access the **grafana** web interface as described in [Accessing the Grafana web UI](#).

5.9. SETTING UP AUTHENTICATION WHILE MONITORING A SYSTEM USING THE METRICS SYSTEM ROLE

PCP supports the **scram-sha-256** authentication mechanism through the Simple Authentication Security Layer (SASL) framework. The metrics RHEL System Role automates the steps to setup authentication using the **scram-sha-256** authentication mechanism. This procedure describes how to

setup authentication using the metrics RHEL System Role.

Prerequisites

- You have Red Hat Ansible Engine installed on the machine you want to use to run the playbook.
- You have the **rhel-system-roles** package installed on the machine you want to use to run the playbook.

Procedure

1. Include the following variables in the Ansible playbook you want to setup authentication for:

```
---
vars:
  metrics_username: your_username
  metrics_password: your_password
```

2. Run the Ansible playbook:

```
# ansible-playbook name_of_your_playbook.yml
```

Verification steps

- Verify the **sasl** configuration:

```
# pminfo -f -h "pcp://ip_adress?username=your_username" disk.dev.read
Password:
disk.dev.read
inst [0 or "sda"] value 19540
```

ip_adress should be replaced by the IP adress of the host.

5.10. USING THE METRICS SYSTEM ROLE TO CONFIGURE AND ENABLE METRICS COLLECTION FOR SQL SERVER

This procedure describes how to use the metrics RHEL System Role to automate the configuration and enabling of metrics collection for Microsoft SQL Server via **pcp** on your local system.

Prerequisites

- You have Red Hat Ansible Engine installed on the machine you want to monitor.
- You have the **rhel-system-roles** package installed on the machine you want to monitor.
- You have installed Microsoft SQL Server for Red Hat Enterprise Linux and established a 'trusted' connection to an SQL server.
- You have installed the Microsoft ODBC driver for SQL Server for Red Hat Enterprise Linux.

Procedure

1. Configure **localhost** in the the **/etc/ansible/hosts** Ansible inventory by adding the following content to the inventory:

```
localhost ansible_connection=local
```

2. Create an Ansible playbook that contains the following content:

```
---
- hosts: localhost
  roles:
    - role: rhel-system-roles.metrics
  vars:
    metrics_from_mssql: yes
```

3. Run the Ansible playbook:

```
# ansible-playbook name_of_your_playbook.yml
```

Verification steps

- Use the **pcp** command to verify that SQL Server PMDA agent (mssql) is loaded and running:

```
# pcp
platform: Linux rhel82-2.local 4.18.0-167.el8.x86_64 #1 SMP Sun Dec 15 01:24:23 UTC
2019 x86_64
hardware: 2 cpus, 1 disk, 1 node, 2770MB RAM
timezone: PDT+7
services: pmcd pmproxy
  pmcd: Version 5.0.2-1, 12 agents, 4 clients
  pmda: root pmcd proc pmproxy xfs linux nfsclient mmv kvm mssql
       jbd2 dm
pmlogger: primary logger: /var/log/pcp/pmlogger/rhel82-2.local/20200326.16.31
pmie: primary engine: /var/log/pcp/pmie/rhel82-2.local/pmie.log
```

Additional resources

- [For more information about using Performance Co-Pilot for Microsoft SQL Server, see this Red Hat Developers Blog post.](#)

[1] This documentation is installed automatically with the **rhel-system-roles** package.

CHAPTER 6. SETTING UP PCP

Performance Co-Pilot (PCP) is a suite of tools, services, and libraries for monitoring, visualizing, storing, and analyzing system-level performance measurements.

This section describes how to install and enable PCP on your system.

6.1. OVERVIEW OF PCP

You can add performance metrics using Python, Perl, C++, and C interfaces. Analysis tools can use the Python, C++, C client APIs directly, and rich web applications can explore all available performance data using a JSON interface.

You can analyze data patterns by comparing live results with archived data.

Features of PCP:

- Light-weight distributed architecture, which is useful during the centralized analysis of complex systems.
- It allows the monitoring and management of real-time data.
- It allows logging and retrieval of historical data.

PCP has the following components:

- The Performance Metric Collector Daemon (**pmcd**) collects performance data from the installed Performance Metric Domain Agents (**pmda**). **PMDAs** can be individually loaded or unloaded on the system and are controlled by the **PMCD** on the same host.
- Various client tools, such as **pminfo** or **pmstat**, can retrieve, display, archive, and process this data on the same host or over the network.
- The **pcp** package provides the command-line tools and underlying functionality.
- The **pcp-gui** package provides the graphical application. Install the **pcp-gui** package by executing the **yum install pcp-gui** command. For more information, see [Visually tracing PCP log archives with the PCP Charts application](#).

Additional resources

- **pcp(1)** man page
- **/usr/share/doc/pcp-doc/** directory
- [Tools distributed with PCP](#)
- [Index of Performance Co-Pilot \(PCP\) articles, solutions, tutorials, and white papers fromon Red Hat Customer Portal](#)
- [Side-by-side comparison of PCP tools with legacy tools Red Hat Knowledgebase article](#)
- [PCP upstream documentation](#)

6.2. INSTALLING AND ENABLING PCP

To begin using PCP, install all the required packages and enable the PCP monitoring services.

This procedure describes how to install PCP using the **pcp** package. If you want to automate the PCP installation, install it using the **pcp-zeroconf** package. For more information on installing PCP by using **pcp-zeroconf**, see [Setting up PCP with pcp-zeroconf](#).

Procedure

1. Install the **pcp** package:

```
# yum install pcp
```

2. Enable and start the **pmcd** service on the host machine:

```
# systemctl enable pmcd
```

```
# systemctl start pmcd
```

Verification steps

- Verify if the **pmcd** process is running on the host:

```
# pcp
```

Performance Co-Pilot configuration on workstation:

```
platform: Linux workstation 4.18.0-80.el8.x86_64 #1 SMP Wed Mar 13 12:02:46 UTC 2019
x86_64
hardware: 12 cpus, 2 disks, 1 node, 36023MB RAM
timezone: CEST-2
services: pmcd
pmcd: Version 4.3.0-1, 8 agents
pmda: root pmcd proc xfs linux mmv kvm jbd2
```

Additional resources

- **pmcd(1)** man page
- [Tools distributed with PCP](#)

6.3. DEPLOYING A MINIMAL PCP SETUP

The minimal PCP setup collects performance statistics on Red Hat Enterprise Linux. The setup involves adding the minimum number of packages on a production system needed to gather data for further analysis.

You can analyze the resulting **tar.gz** file and the archive of the **pmlogger** output using various PCP tools and compare them with other sources of performance information.

Prerequisites

- PCP is installed. For more information, see [Installing and enabling PCP](#).

Procedure

1. Update the **pmlogger** configuration:

```
# pmlogconf -r /var/lib/pcp/config/pmlogger/config.default
```

2. Start the **pmcd** and **pmlogger** services:

```
# systemctl start pmcd.service
# systemctl start pmlogger.service
```

3. Execute the required operations to record the performance data.

4. Stop the **pmcd** and **pmlogger** services:

```
# systemctl stop pmcd.service
# systemctl stop pmlogger.service
```

5. Save the output and save it to a **tar.gz** file named based on the host name and the current date and time:

```
# cd /var/log/pcp/pmlogger/
# tar -czf $(hostname).$(date +%F-%H%M).pcp.tar.gz $(hostname)
```

Extract this file and analyze the data using PCP tools.

Additional resources

- **pmlogconf(1)**, **pmlogger(1)**, and **pmcd(1)** man pages
- [Tools distributed with PCP](#)
- [System services distributed with PCP](#)

6.4. SYSTEM SERVICES DISTRIBUTED WITH PCP

The following table describes roles of various system services, which are distributed with PCP.

Table 6.1. Roles of system services distributed with PCP

Name	Description
pmcd	The Performance Metric Collector Daemon (PMCD).
pmie	The Performance Metrics Inference Engine.
pmlogger	The performance metrics logger.

pmproxy	The realtime and historical performance metrics proxy, time series query and REST API service.
----------------	--

6.5. TOOLS DISTRIBUTED WITH PCP

The following table describes usage of various tools, which are distributed with PCP.

Table 6.2. Usage of tools distributed with PCP

Name	Description
pcp	Displays the current status of a Performance Co-Pilot installation.
pcp-atop	Shows the system-level occupation of the most critical hardware resources from the performance point of view: CPU, memory, disk, and network.
pcp-atopsar	Generates a system-level activity report over a variety of system resource utilization. The report is generated from a raw logfile previously recorded using pmlogger or the <code>-w</code> option of pcp-atop.
pcp-dmcache	Displays information about configured Device Mapper Cache targets, such as: device IOPs, cache and metadata device utilization, as well as hit and miss rates and ratios for both reads and writes for each cache device.
pcp-dstat	Displays metrics of one system at a time. To display metrics of multiple systems, use --host option.
pcp-free	Reports on free and used memory in a system.
pcp-htop	Displays all processes running on a system along with their command line arguments in a manner similar to the top command, but allows you to scroll vertically and horizontally as well as interact using a mouse. You can also view processes in a tree format and select and act on multiple processes at once.
pcp-ipcs	Displays information on the inter-process communication (IPC) facilities that the calling process has read access for.
pcp-numastat	Displays NUMA allocation statistics from the kernel memory allocator.

pcp-pidstat	Displays information about individual tasks or processes running on the system such as: CPU percentage, memory and stack usage, scheduling, and priority. Reports live data for the local host by default.
pcp-ss	Displays socket statistics collected by the pmdasockets Performance Metrics Domain Agent (PMDA).
pcp-uptime	Displays how long the system has been running, how many users are currently logged on, and the system load averages for the past 1, 5, and 15 minutes.
pcp-vmstat	Provides a high-level system performance overview every 5 seconds. Displays information about processes, memory, paging, block IO, traps, and CPU activity.
pmchart	Plots performance metrics values available through the facilities of the Performance Co-Pilot.
pmclient	Displays high-level system performance metrics by using the Performance Metrics Application Programming Interface (PMAPI).
pmconfig	Displays the values of configuration parameters.
pmdbg	Displays available Performance Co-Pilot debug control flags and their values.
pmdiff	Compares the average values for every metric in either one or two archives, in a given time window, for changes that are likely to be of interest when searching for performance regressions.
pmdumplog	Displays control, metadata, index, and state information from a Performance Co-Pilot archive file.
pmdumptext	Outputs the values of performance metrics collected live or from a Performance Co-Pilot archive.
pmerr	Displays available Performance Co-Pilot error codes and their corresponding error messages.
pmfind	Finds PCP services on the network.

pmie	An inference engine that periodically evaluates a set of arithmetic, logical, and rule expressions. The metrics are collected either from a live system, or from a Performance Co-Pilot archive file.
pmieconf	Displays or sets configurable pmie variables.
pmiectl	Manages non-primary instances of pmie.
pminfo	Displays information about performance metrics. The metrics are collected either from a live system, or from a Performance Co-Pilot archive file.
pmiostat	Reports I/O statistics for SCSI devices (by default) or device-mapper devices (with the <code>-x dm</code> option).
pmic	Interactively configures active pmlogger instances.
pmlogcheck	Identifies invalid data in a Performance Co-Pilot archive file.
pmlogconf	Creates and modifies a pmlogger configuration file.
pmlogctl	Manages non-primary instances of pmlogger.
pmloglabel	Verifies, modifies, or repairs the label of a Performance Co-Pilot archive file.
pmlogsummary	Calculates statistical information about performance metrics stored in a Performance Co-Pilot archive file.
pmprobe	Determines the availability of performance metrics.
pmrep	Reports on selected, easily customizable, performance metrics values.
pmsocks	Allows access to a Performance Co-Pilot hosts through a firewall.
pmstat	Periodically displays a brief summary of system performance.
pmstore	Modifies the values of performance metrics.
pmtrace	Provides a command line interface to the trace PMDA.
pmval	Displays the current value of a performance metric.

6.6. PCP DEPLOYMENT ARCHITECTURES

Performance Co-Pilot (PCP) offers many options to accomplish advanced setups. From the huge variety of possible architectures, this section describes how to scale your PCP deployment based on the recommended deployment set up by Red Hat, sizing factors, and configuration options.

PCP supports multiple deployment architectures, based on the scale of the PCP deployment.

Available scaling deployment setup variants:

NOTE

Since the PCP version 5.3.0 is unavailable in Red Hat Enterprise Linux 8.4 and the prior minor versions of Red Hat Enterprise Linux 8, Red Hat recommends localhost and pmlogger farm architectures.

For more information about known memory leaks in pmproxy in PCP versions before 5.3.0, see [Memory leaks in pmproxy in PCP](#).

Localhost

Each service runs locally on the monitored machine. When you start a service without any configuration changes, this is the default deployment. Scaling beyond the individual node is not possible in this case.

By default, the deployment setup for Redis is standalone, localhost. However, Redis can optionally perform in a highly-available and highly scalable clustered fashion, where data is shared across multiple hosts. Another viable option is to deploy a Redis cluster in the cloud, or to utilize a managed Redis cluster from a cloud vendor.

Decentralized

The only difference between localhost and decentralized setup is the centralized Redis service. In this model, the host executes **pmlogger** service on each monitored host and retrieves metrics from a local **pmcd** instance. A local **pmproxy** service then exports the performance metrics to a central Redis instance.

Figure 6.1. Decentralized logging

173_RHEL_0721

Centralized logging - pmlogger farm

When the resource usage on the monitored hosts is constrained, another deployment option is a **pmlogger** farm, which is also known as centralized logging. In this setup, a single logger host executes multiple **pmlogger** processes, and each is configured to retrieve performance metrics from a different remote **pmcd** host. The centralized logger host is also configured to execute the **pmproxy** service, which discovers the resulting PCP archives logs and loads the metric data into a Redis instance.

Figure 6.2. Centralized logging - pmlogger farm

Federated - multiple pmlogger farms

For large scale deployments, Red Hat recommends to deploy multiple **pmlogger** farms in a federated fashion. For example, one **pmlogger** farm per rack or data center. Each **pmlogger** farm loads the metrics into a central Redis instance.

Figure 6.3. Federated - multiple pmlogger farms

173_RHEL_0721

**NOTE**

By default, the deployment setup for Redis is standalone, localhost. However, Redis can optionally perform in a highly-available and highly scalable clustered fashion, where data is shared across multiple hosts. Another viable option is to deploy a Redis cluster in the cloud, or to utilize a managed Redis cluster from a cloud vendor.

Additional resources

- **pcp(1)**, **pmlogger(1)**, **pmproxy(1)**, and **pmcd(1)** man pages
- [Recommended deployment architecture](#)

6.7. RECOMMENDED DEPLOYMENT ARCHITECTURE

The following table describes the recommended deployment architectures based on the number of monitored hosts.

Table 6.3. Recommended deployment architecture

Number of hosts (N)	1-10	10-100	100-1000
pmcd servers	N	N	N
pmlogger servers	1 to N	N/10 to N	N/100 to N
pmproxy servers	1 to N	1 to N	N/100 to N
Redis servers	1 to N	1 to N/10	N/100 to N/10
Redis cluster	No	Maybe	Yes
Recommended deployment setup	Localhost, Decentralized, or Centralized logging	Decentralized, Centralized logging, or Federated	Decentralized or Federated

6.8. SIZING FACTORS

The following are the sizing factors required for scaling:

Remote system size

The number of CPUs, disks, network interfaces, and other hardware resources affects the amount of data collected by each **pmlogger** on the centralized logging host.

Logged Metrics

The number and types of logged metrics play an important role. In particular, the **per-process proc.*** metrics require a large amount of disk space, for example, with the standard **pcp-zeroconf** setup, 10s logging interval, 11 MB without proc metrics versus 155 MB with proc metrics – a factor of 10 times more. Additionally, the number of instances for each metric, for example the number of CPUs, block devices, and network interfaces also impacts the required storage capacity.

Logging Interval

The interval how often metrics are logged, affects the storage requirements. The expected daily PCP archive file sizes are written to the **pmlogger.log** file for each **pmlogger** instance. These values are uncompressed estimates. Since PCP archives compress very well, approximately 10:1, the actual long term disk space requirements can be determined for a particular site.

pmlogrewrite

After every PCP upgrade, the **pmlogrewrite** tool is executed and rewrites old archives if there were changes in the metric metadata from the previous version and the new version of PCP. This process duration scales linear with the number of archives stored.

Additional resources

- **pmlogrewrite(1)** and **pmlogger(1)** man pages

6.9. CONFIGURATION OPTIONS FOR PCP SCALING

The following are the configuration options, which are required for scaling:

sysctl and rlimit settings

When archive discovery is enabled, **pmproxy** requires four descriptors for every **pmlogger** that it is monitoring or log-tailing, along with the additional file descriptors for the service logs and **pmproxy** client sockets, if any. Each **pmlogger** process uses about 20 file descriptors for the remote **pmcd** socket, archive files, service logs, and others. In total, this can exceed the default 1024 soft limit on a system running around 200 **pmlogger** processes. The **pmproxy** service in **pcp-5.3.0** and later automatically increases the soft limit to the hard limit. On earlier versions of PCP, tuning is required if a high number of **pmlogger** processes are to be deployed, and this can be accomplished by increasing the soft or hard limits for **pmlogger**. For more information, see [How to set limits \(ulimit\) for services run by systemd](#).

Local Archives

The **pmlogger** service stores metrics of local and remote **pmcds** in the **/var/log/pcp/pmlogger/** directory. To control the logging interval of the local system, update the **/etc/pcp/pmlogger/control.d/configfile** file and add **-t X** in the arguments, where **X** is the logging interval in seconds. To configure which metrics should be logged, execute **pmlogconf /var/lib/pcp/config/pmlogger/config.clienthostname**. This command deploys a configuration file with a default set of metrics, which can optionally be further customized. To specify retention settings, that is when to purge old PCP archives, update the **/etc/sysconfig/pmlogger_timers** file and specify **PMLOGGER_DAILY_PARAMS="-E -k X"**, where **X** is the amount of days to keep PCP archives.

Redis

The **pmproxy** service sends logged metrics from **pmlogger** to a Redis instance. The following are the available two options to specify the retention settings in the **/etc/pcp/pmproxy/pmproxy.conf** configuration file:

- **stream.expire** specifies the duration when stale metrics should be removed, that is metrics which were not updated in a specified amount of time in seconds.
- **stream.maxlen** specifies the maximum number of metric values for one metric per host. This setting should be the retention time divided by the logging interval, for example 20160 for 14 days of retention and 60s logging interval ($60 \times 60 \times 24 \times 14 / 60$)

Additional resources

- **pmproxy(1)**, **pmlogger(1)**, and **sysctl(8)** man pages

6.10. EXAMPLE: ANALYZING THE CENTRALIZED LOGGING DEPLOYMENT

The following results were gathered on a centralized logging setup, also known as **pmlogger** farm deployment, with a default **pcp-zeroconf 5.3.0** installation, where each remote host is an identical container instance running **pmcd** on a server with 64 CPU cores, 376 GB RAM, and one disk attached.

The logging interval is 10s, proc metrics of remote nodes are not included, and the memory values refer to the Resident Set Size (RSS) value.

Table 6.4. Detailed utilization statistics for 10s logging interval

Number of Hosts	10	50
PCP Archives Storage per Day	91 MB	522 MB
pmlogger Memory	160 MB	580 MB
pmlogger Network per Day (In)	2 MB	9 MB
pmproxy Memory	1.4 GB	6.3 GB
Redis Memory per Day	2.6 GB	12 GB

Table 6.5. Used resources depending on monitored hosts for 60s logging interval

Number of Hosts	10	50	100
PCP Archives Storage per Day	20 MB	120 MB	271 MB
pmlogger Memory	104 MB	524 MB	1049 MB
pmlogger Network per Day (In)	0.38 MB	1.75 MB	3.48 MB
pmproxy Memory	2.67 GB	5.5GB	9 GB
Redis Memory per Day	0.54 GB	2.65 GB	5.3 GB

NOTE

The **pmproxy** queues Redis requests and employs Redis pipelining to speed up Redis queries. This can result in high memory usage. For troubleshooting this issue, see [Troubleshooting high memory usage](#).

6.11. EXAMPLE: ANALYZING THE FEDERATED SETUP DEPLOYMENT

The following results were observed on a federated setup, also known as multiple **pmlogger** farms, consisting of three centralized logging (**pmlogger** farm) setups, where each **pmlogger** farm was monitoring 100 remote hosts, that is 300 hosts in total.

This setup of the **pmlogger** farms is identical to the configuration mentioned in the [Example: Analyzing the centralized logging deployment](#) for 60s logging interval, except that the Redis servers were operating in cluster mode.

Table 6.6. Used resources depending on federated hosts for 60s logging interval

PCP Archives Storage per Day	pmlogger Memory	Network per Day (In/Out)	pmproxy Memory	Redis Memory per Day
277 MB	1058 MB	15.6 MB / 12.3 MB	6-8 GB	5.5 GB

Here, all values are per host. The network bandwidth is higher due to the inter-node communication of the Redis cluster.

6.12. TROUBLESHOOTING HIGH MEMORY USAGE

The following scenarios can result in high memory usage:

- The **pmproxy** process is busy processing new PCP archives and does not have spare CPU cycles to process Redis requests and responses.
- The Redis node or cluster is overloaded and cannot process incoming requests on time.

The **pmproxy** service daemon uses Redis streams and supports the configuration parameters, which are PCP tuning parameters and affects Redis memory usage and key retention. The `/etc/pcp/pmproxy/pmproxy.conf` file lists the available configuration options for **pmproxy** and the associated APIs.

This section describes how to troubleshoot high memory usage issue.

Prerequisites

1. Install the **pcp-pmda-redis** package:

```
# yum install pcp-pmda-redis
```

2. Install the redis PMDA:

```
# cd /var/lib/pcp/pmdas/redis && ./Install
```

Procedure

- To troubleshoot high memory usage, execute the following command and observe the **inflight** column:

```
$ pmrep :pmproxy
      backlog inflight reqs/s resp/s  wait req err resp err changed throttled
      byte   count  count/s count/s  s/s count/s count/s count/s count/s
14:59:08  0      0    N/A    N/A  N/A  N/A  N/A  N/A  N/A  N/A
14:59:09  0      0  2268.9  2268.9  28   0    0    2.0   4.0
14:59:10  0      0    0.0    0.0   0    0    0    0.0   0.0
14:59:11  0      0    0.0    0.0   0    0    0    0.0   0.0
```

This column shows how many Redis requests are in-flight, which means they are queued or sent, and no reply was received so far.

A high number indicates one of the following conditions:

- The **pmproxy** process is busy processing new PCP archives and does not have spare CPU cycles to process Redis requests and responses.
- The Redis node or cluster is overloaded and cannot process incoming requests on time.
- To troubleshoot the high memory usage issue, reduce the number of **pmlogger** processes for this farm, and add another pmlogger farm. Use the federated - multiple pmlogger farms setup. If the Redis node is using 100% CPU for an extended amount of time, move it to a host with better performance or use a clustered Redis setup instead.
- To view the **pmproxy.redis.*** metrics, use the following command:

```
$ pminfo -ftd pmproxy.redis
pmproxy.redis.responses.wait [wait time for responses]
  Data Type: 64-bit unsigned int InDom: PM_INDOM_NULL 0xffffffff
  Semantics: counter Units: microsec
  value 546028367374
pmproxy.redis.responses.error [number of error responses]
  Data Type: 64-bit unsigned int InDom: PM_INDOM_NULL 0xffffffff
  Semantics: counter Units: count
  value 1164
[...]
pmproxy.redis.requests.inflight.bytes [bytes allocated for inflight requests]
  Data Type: 64-bit int InDom: PM_INDOM_NULL 0xffffffff
  Semantics: discrete Units: byte
  value 0

pmproxy.redis.requests.inflight.total [inflight requests]
  Data Type: 64-bit unsigned int InDom: PM_INDOM_NULL 0xffffffff
  Semantics: discrete Units: count
  value 0
[...]
```

To view how many Redis requests are inflight, see the **pmproxy.redis.requests.inflight.total** metric and **pmproxy.redis.requests.inflight.bytes** metric to view how many bytes are occupied by all current inflight Redis requests.

In general, the redis request queue would be zero but can build up based on the usage of large pmlogger farms, which limits scalability and can cause high latency for **pmproxy** clients.

- Use the **pminfo** command to view information about performance metrics. For example, to view the **redis.*** metrics, use the following command:

```
$ pminfo -ftd redis
redis.redis_build_id [Build ID]
  Data Type: string InDom: 24.0 0x6000000
  Semantics: discrete Units: count
  inst [0 or "localhost:6379"] value "87e335e57cfa755"
redis.total_commands_processed [Total number of commands processed by the server]
  Data Type: 64-bit unsigned int InDom: 24.0 0x6000000
  Semantics: counter Units: count
```

```
inst [0 or "localhost:6379"] value 595627069
[...]

redis.used_memory_peak [Peak memory consumed by Redis (in bytes)]
  Data Type: 32-bit unsigned int InDom: 24.0 0x6000000
  Semantics: instant Units: count
  inst [0 or "localhost:6379"] value 572234920
  [...]
```

To view the peak memory usage, see the **redis.used_memory_peak** metric.

- **pmdaredis(1)**, **pmproxy(1)**, and **pminfo(1)** man pages
- [PCP deployment architectures](#)

CHAPTER 7. LOGGING PERFORMANCE DATA WITH PMLOGGER

With the PCP tool you can log the performance metric values and replay them later. This allows you to perform a retrospective performance analysis.

Using the **pmlogger** tool, you can:

- Create the archived logs of selected metrics on the system
- Specify which metrics are recorded on the system and how often

7.1. MODIFYING THE PMLOGGER CONFIGURATION FILE WITH PMLOGCONF

When the **pmlogger** service is running, PCP logs a default set of metrics on the host.

Use the **pmlogconf** utility to check the default configuration. If the **pmlogger** configuration file does not exist, **pmlogconf** creates it with a default metric values.

Prerequisites

- PCP is installed. For more information, see [Installing and enabling PCP](#).

Procedure

1. Create or modify the **pmlogger** configuration file:

```
# pmlogconf -r /var/lib/pcp/config/pmlogger/config.default
```

2. Follow **pmlogconf** prompts to enable or disable groups of related performance metrics and to control the logging interval for each enabled group.

Additional resources

- **pmlogconf(1)** and **pmlogger(1)** man pages
- [Tools distributed with PCP](#)
- [System services distributed with PCP](#)

7.2. EDITING THE PMLOGGER CONFIGURATION FILE MANUALLY

To create a tailored logging configuration with specific metrics and given intervals, edit the **pmlogger** configuration file manually. The default **pmlogger** configuration file is **/var/lib/pcp/config/pmlogger/config.default**. The configuration file specifies which metrics are logged by the primary logging instance.

In manual configuration, you can:

- Record metrics which are not listed in the automatic configuration.
- Choose custom logging frequencies.

- Add **PMDA** with the application metrics.

Prerequisites

- PCP is installed. For more information, see [Installing and enabling PCP](#).

Procedure

- Open and edit the **/var/lib/pcp/config/pmlogger/config.default** file to add specific metrics:

```
# It is safe to make additions from here on ...
#

log mandatory on every 5 seconds {
    xfs.write
    xfs.write_bytes
    xfs.read
    xfs.read_bytes
}

log mandatory on every 10 seconds {
    xfs.allocs
    xfs.block_map
    xfs.transactions
    xfs.log
}

[access]
disallow * : all;
allow localhost : enquire;
```

Additional resources

- **pmlogger(1)** man page
- [Tools distributed with PCP](#)
- [System services distributed with PCP](#)

7.3. ENABLING THE PMLOGGER SERVICE

The **pmlogger** service must be started and enabled to log the metric values on the local machine.

This procedure describes how to enable the **pmlogger** service.

Prerequisites

- PCP is installed. For more information, see [Installing and enabling PCP](#).

Procedure

- Start and enable the **pmlogger** service:

```
# systemctl start pmlogger
# systemctl enable pmlogger
```

Verification steps

- Verify if the **pmlogger** service is enabled:

```
# pcg

Performance Co-Pilot configuration on workstation:

platform: Linux workstation 4.18.0-80.el8.x86_64 #1 SMP Wed Mar 13 12:02:46 UTC 2019
x86_64
hardware: 12 cpus, 2 disks, 1 node, 36023MB RAM
timezone: CEST-2
services: pmcd
pmcd: Version 4.3.0-1, 8 agents, 1 client
pmda: root pmcd proc xfs linux mmv kvm jbd2
pmlogger: primary logger: /var/log/pcp/pmlogger/workstation/20190827.15.54
```

Additional resources

- **pmlogger(1)** man page
- [Tools distributed with PCP](#)
- [System services distributed with PCP](#)
- `/var/lib/pcp/config/pmlogger/config.default` file

7.4. SETTING UP A CLIENT SYSTEM FOR METRICS COLLECTION

This procedure describes how to set up a client system so that a central server can collect metrics from clients running PCP.

Prerequisites

- PCP is installed. For more information, see [Installing and enabling PCP](#).

Procedure

1. Install the **pcp-system-tools** package:

```
# yum install pcp-system-tools
```

2. Configure an IP address for **pmcd**:

```
# echo "-i 192.168.4.62" >>/etc/pcp/pmcd/pmcd.options
```

Replace `192.168.4.62` with the IP address, the client should listen on.

By default, **pmcd** is listening on the localhost.

3. Configure the firewall to add the public **zone** permanently:

```
# firewall-cmd --permanent --zone=public --add-port=44321/tcp
success

# firewall-cmd --reload
success
```

4. Set an SELinux boolean:

```
# setsebool -P pcp_bind_all_unreserved_ports on
```

5. Enable the **pmcd** and **pmlogger** services:

```
# systemctl enable pmcd pmlogger
# systemctl restart pmcd pmlogger
```

Verification steps

- Verify if the **pmcd** is correctly listening on the configured IP address:

```
# ss -tln | grep 44321
LISTEN 0 5 127.0.0.1:44321 0.0.0.0:* users:(("pmcd",pid=151595,fd=6))
LISTEN 0 5 192.168.4.62:44321 0.0.0.0:* users:(("pmcd",pid=151595,fd=0))
LISTEN 0 5 :::44321 :::* users:(("pmcd",pid=151595,fd=7))
```

Additional resources

- **pmlogger(1)**, **firewall-cmd(1)**, **ss(8)**, and **setsebool(8)** man pages
- [Tools distributed with PCP](#)
- [System services distributed with PCP](#)
- **/var/lib/pcp/config/pmlogger/config.default** file

7.5. SETTING UP A CENTRAL SERVER TO COLLECT DATA

This procedure describes how to create a central server to collect metrics from clients running PCP.

Prerequisites

- PCP is installed. For more information, see [Installing and enabling PCP](#).
- Client is configured for metrics collection. For more information, see [Setting up a client system for metrics collection](#).

Procedure

1. Install the **pcp-system-tools** package:

```
# yum install pcp-system-tools
```

2. Create the `/etc/pcp/pmlogger/control.d/remote` file with the following content:

```
# DO NOT REMOVE OR EDIT THE FOLLOWING LINE
$version=1.1

192.168.4.13 n n PCP_LOG_DIR/pmlogger/rhel7u4a -r -T24h10m -c config.rhel7u4a
192.168.4.14 n n PCP_LOG_DIR/pmlogger/rhel6u10a -r -T24h10m -c config.rhel6u10a
192.168.4.62 n n PCP_LOG_DIR/pmlogger/rhel8u1a -r -T24h10m -c config.rhel8u1a
```

Replace `192.168.4.13`, `192.168.4.14`, and `192.168.4.62` with the client IP addresses.

3. Enable the **pmcd** and **pmlogger** services:

```
# systemctl enable pmcd pmlogger
# systemctl restart pmcd pmlogger
```

Verification steps

- Ensure that you can access the latest archive file from each directory:

```
# for i in /var/log/pcp/pmlogger/rhel*/*.0; do pmdumplog -L $i; done
Log Label (Log Format Version 2)
Performance metrics from host rhel6u10a.local
commencing Mon Nov 25 21:55:04.851 2019
ending Mon Nov 25 22:06:04.874 2019
Archive timezone: JST-9
PID for pmlogger: 24002
Log Label (Log Format Version 2)
Performance metrics from host rhel7u4a
commencing Tue Nov 26 06:49:24.954 2019
ending Tue Nov 26 07:06:24.979 2019
Archive timezone: CET-1
PID for pmlogger: 10941
[..]
```

The archive files from the `/var/log/pcp/pmlogger/` directory can be used for further analysis and graphing.

Additional resources

- **pmlogger(1)** man page
- [Tools distributed with PCP](#)
- [System services distributed with PCP](#)
- `/var/lib/pcp/config/pmlogger/config.default` file

7.6. REPLAYING THE PCP LOG ARCHIVES WITH PMREP

After recording the metric data, you can replay the PCP log archives. To export the logs to text files and import them into spreadsheets, use PCP utilities such as **pcp2csv**, **pcp2xml**, **pmrep** or **pmlogsummary**.

Using the **pmrep** tool, you can:

- View the log files
- Parse the selected PCP log archive and export the values into an ASCII table
- Extract the entire archive log or only select metric values from the log by specifying individual metrics on the command line

Prerequisites

- PCP is installed. For more information, see [Installing and enabling PCP](#).
- The **pmlogger** service is enabled. For more information, see [Enabling the pmlogger service](#).
- Install the **pcp-system-tools** package:

```
# yum install pcp-gui
```

Procedure

- Display the data on the metric:

```
$ pmrep --start @3:00am --archive 20211128 --interval 5seconds --samples 10 --output csv
disk.dev.write
Time,"disk.dev.write-sda","disk.dev.write-sdb"
2021-11-28 03:00:00,,
2021-11-28 03:00:05,4.000,5.200
2021-11-28 03:00:10,1.600,7.600
2021-11-28 03:00:15,0.800,7.100
2021-11-28 03:00:20,16.600,8.400
2021-11-28 03:00:25,21.400,7.200
2021-11-28 03:00:30,21.200,6.800
2021-11-28 03:00:35,21.000,27.600
2021-11-28 03:00:40,12.400,33.800
2021-11-28 03:00:45,9.800,20.600
```

The mentioned example displays the data on the **disk.dev.write** metric collected in an archive at a 5 *second* interval in comma-separated-value format.

NOTE

Replace **20211128** in this example with a filename containing the **pmlogger** archive you want to display data for.

Additional resources

- **pmlogger(1)**, **pmrep(1)**, and **pmlogsummary(1)** man pages
- [Tools distributed with PCP](#)
- [System services distributed with PCP](#)

CHAPTER 8. MONITORING PERFORMANCE WITH PERFORMANCE CO-PILOT

Performance Co-Pilot (PCP) is a suite of tools, services, and libraries for monitoring, visualizing, storing, and analyzing system-level performance measurements.

As a system administrator, you can monitor the system's performance using the the PCP application in Red Hat Enterprise Linux 8.

8.1. MONITORING POSTFIX WITH PMDA-POSTFIX

This procedure describes how to monitor performance metrics of the **postfix** mail server with **pmda-postfix**. It helps to check how many emails are received per second.

Prerequisites

- PCP is installed. For more information, see [Installing and enabling PCP](#).
- The **pmlogger** service is enabled. For more information, see [Enabling the pmlogger service](#).

Procedure

1. Install the following packages:

- a. Install the **pcp-system-tools**:

```
# yum install pcp-system-tools
```

- b. Install the **pmda-postfix** package to monitor **postfix**:

```
# yum install pcp-pmda-postfix postfix
```

- c. Install the logging daemon:

```
# yum install rsyslog
```

- d. Install the mail client for testing:

```
# yum install mutt
```

2. Enable the **postfix** and **rsyslog** services:

```
# systemctl enable postfix rsyslog  
# systemctl restart postfix rsyslog
```

3. Enable the SELinux boolean, so that **pmda-postfix** can access the required log files:

```
# setsebool -P pcp_read_generic_logs=on
```

4. Install the **PMDA**:

```
# cd /var/lib/pcp/pmdas/postfix/
```

```
# ./Install
```

```
Updating the Performance Metrics Name Space (PMNS) ...
Terminate PMDA if already installed ...
Updating the PMCD control file, and notifying PMCD ...
Waiting for pmcd to terminate ...
Starting pmcd ...
Check postfix metrics have appeared ... 7 metrics and 58 values
```

Verification steps

- Verify the **pmda-postfix** operation:

```
echo testmail | mutt root
```

- Verify the available metrics:

```
# pminfo postfix

postfix.received
postfix.sent
postfix.queues.incoming
postfix.queues.maildrop
postfix.queues.hold
postfix.queues.deferred
postfix.queues.active
```

Additional resources

- **rsyslogd(8)**, **postfix(1)**, and **setsebool(8)** man pages
- [Tools distributed with PCP](#)
- [System services distributed with PCP](#)
- **/var/lib/pcp/config/pmlogger/config.default** file

8.2. VISUALLY TRACING PCP LOG ARCHIVES WITH THE PCP CHARTS APPLICATION

After recording metric data, you can replay the PCP log archives as graphs. The metrics are sourced from one or more live hosts with alternative options to use metric data from PCP log archives as a source of historical data. To customize the **PCP Charts** application interface to display the data from the performance metrics, you can use line plot, bar graphs, or utilization graphs.

Using the **PCP Charts** application, you can:

- Replay the data in the **PCP Charts** application and use graphs to visualize the retrospective data alongside live data of the system.
- Plot performance metric values into graphs.
- Display multiple charts simultaneously.

Prerequisites

- PCP is installed. For more information, see [Installing and enabling PCP](#).
- Logged performance data with the **pmlogger**. For more information, see [Logging performance data with pmlogger](#).
- Install the **pcp-gui** package:

```
# yum install pcp-gui
```

Procedure

1. Launch the **PCP Charts** application from the command line:

```
# pmchart
```

Figure 8.1. PCP Charts application

The **pmtime** server settings are located at the bottom. The **start** and **pause** button allows you to control:

- The interval in which PCP polls the metric data
 - The date and time for the metrics of historical data
2. Click **File** and then **New Chart** to select metric from both the local machine and remote machines by specifying their host name or address. Advanced configuration options include the ability to manually set the axis values for the chart, and to manually choose the color of the plots.
 3. Record the views created in the **PCP Charts** application:
Following are the options to take images or record the views created in the **PCP Charts** application:
 - Click **File** and then **Export** to save an image of the current view.

- Click **Record** and then **Start** to start a recording. Click **Record** and then **Stop** to stop the recording. After stopping the recording, the recorded metrics are archived to be viewed later.
4. Optional: In the **PCP Charts** application, the main configuration file, known as the **view**, allows the metadata associated with one or more charts to be saved. This metadata describes all chart aspects, including the metrics used and the chart columns. Save the custom **view** configuration by clicking **File** and then **Save View**, and load the **view** configuration later.
- The following example of the **PCP Charts** application view configuration file describes a stacking chart graph showing the total number of bytes read and written to the given XFS file system **loop1**:

```
#kmchart
version 1

chart title "Filesystem Throughput /loop1" style stacking antialiasing off
plot legend "Read rate" metric xfs.read_bytes instance "loop1"
plot legend "Write rate" metric xfs.write_bytes instance "loop1"
```

Additional resources

- **pmchart(1)** and **pmtime(1)** man pages
- [Tools distributed with PCP](#)

8.3. COLLECTING DATA FROM SQL SERVER USING PCP

With Red Hat Enterprise Linux 8.2 or later, the SQL Server agent is available in Performance Co-Pilot (PCP), which helps you to monitor and analyze database performance issues.

This procedure describes how to collect data for Microsoft SQL Server via **pcp** on your system.

Prerequisites

- You have installed Microsoft SQL Server for Red Hat Enterprise Linux and established a 'trusted' connection to an SQL server.
- You have installed the Microsoft ODBC driver for SQL Server for Red Hat Enterprise Linux.

Procedure

1. Install PCP:

```
# yum install pcp-zeroconf
```

2. Install packages required for the **pyodbc** driver:

```
# yum install gcc-c++ python3-devel unixODBC-devel
```

```
# yum install python3-pyodbc
```

3. Install the **mssql** agent:

- a. Install the Microsoft SQL Server domain agent for PCP:

```
# yum install pcp-pmda-mssql
```

- b. Edit the `/etc/pcp/mssql/mssql.conf` file to configure the SQL server account's username and password for the **mssql** agent. Ensure that the account you configure has access rights to performance data.

```
username: user_name
password: user_password
```

Replace *user_name* with the SQL Server account and *user_password* with the SQL Server user password for this account.

4. Install the agent:

```
# cd /var/lib/pcp/pmdas/mssql
# ./Install
Updating the Performance Metrics Name Space (PMNS) ...
Terminate PMDA if already installed ...
Updating the PMCD control file, and notifying PMCD ...
Check mssql metrics have appeared ... 168 metrics and 598 values
[...]
```

Verification steps

- Using the **pcp** command, verify if the SQL Server PMDA (**mssql**) is loaded and running:

```
$ pcp
Performance Co-Pilot configuration on rhel.local:

platform: Linux rhel.local 4.18.0-167.el8.x86_64 #1 SMP Sun Dec 15 01:24:23 UTC 2019
x86_64
hardware: 2 cpus, 1 disk, 1 node, 2770MB RAM
timezone: PDT+7
services: pmcd pmproxy
  pmcd: Version 5.0.2-1, 12 agents, 4 clients
  pmda: root pmcd proc pmproxy xfs linux nfsclient mmv kvm mssql
        jbd2 dm
pmlogger: primary logger: /var/log/pcp/pmlogger/rhel.local/20200326.16.31
pmie: primary engine: /var/log/pcp/pmie/rhel.local/pmie.log
```

- View the complete list of metrics that PCP can collect from the SQL Server:

```
# pminfo mssql
```

- After viewing the list of metrics, you can report the rate of transactions. For example, to report on the overall transaction count per second, over a five second time window:

```
# pmval -t 1 -T 5 mssql.databases.transactions
```

- View the graphical chart of these metrics on your system by using the **pmchart** command. For more information, see [Visually tracing PCP log archives with the PCP Charts application](#).

Additional resources

- **pcp(1)**, **pminfo(1)**, **pmval(1)**, **pmchart(1)**, and **pmdamssql(1)** man pages
- [Performance Co-Pilot for Microsoft SQL Server with RHEL 8.2 Red Hat Developers Blog post](#)

CHAPTER 9. PERFORMANCE ANALYSIS OF XFS WITH PCP

The XFS PMDA ships as part of the **pcp** package and is enabled by default during the installation. It is used to gather performance metric data of XFS file systems in Performance Co-Pilot (PCP).

This section describes how to analyze XFS file system's performance using PCP.

9.1. INSTALLING XFS PMDA MANUALLY

If the XFS PMDA is not listed in the **pcp** configuration output, install the PMDA agent manually.

This procedure describes how to manually install the PMDA agent.

Prerequisites

- PCP is installed. For more information, see [Installing and enabling PCP](#).

Procedure

1. Navigate to the xfs directory:

```
# cd /var/lib/pcp/pmdas/xfs/
```

Verification steps

- Verify that the **pmcd** process is running on the host and the XFS PMDA is listed as enabled in the configuration:

```
# pcp
```

Performance Co-Pilot configuration on workstation:

```
platform: Linux workstation 4.18.0-80.el8.x86_64 #1 SMP Wed Mar 13 12:02:46 UTC 2019
x86_64
hardware: 12 cpus, 2 disks, 1 node, 36023MB RAM
timezone: CEST-2
services: pmcd
pmcd: Version 4.3.0-1, 8 agents
pmda: root pmcd proc xfs linux mmv kvm jbd2
```

Additional resources

- **pmcd(1)** man page
- [Tools distributed with PCP](#)

9.2. EXAMINING XFS PERFORMANCE METRICS WITH PMINFO

PCP enables XFS PMDA to allow the reporting of certain XFS metrics per each of the mounted XFS file systems. This makes it easier to pinpoint specific mounted file system issues and evaluate performance.

The **pminfo** command provides per-device XFS metrics for each mounted XFS file system.

This procedure displays a list of all available metrics provided by the XFS PMDA.

Prerequisites

- PCP is installed. For more information, see [Installing and enabling PCP](#).

Procedure

- Display the list of all available metrics provided by the XFS PMDA:

```
# pminfo xfs
```

- Display information for the individual metrics. The following examples examine specific XFS **read** and **write** metrics using the **pminfo** tool:

- Display a short description of the **xfs.write_bytes** metric:

```
# pminfo --online xfs.write_bytes

xfs.write_bytes [number of bytes written in XFS file system write operations]
```

- Display a long description of the **xfs.read_bytes** metric:

```
# pminfo --helptext xfs.read_bytes

xfs.read_bytes
Help:
This is the number of bytes read via read(2) system calls to files in
XFS file systems. It can be used in conjunction with the read_calls
count to calculate the average size of the read operations to file in
XFS file systems.
```

- Obtain the current performance value of the **xfs.read_bytes** metric:

```
# pminfo --fetch xfs.read_bytes

xfs.read_bytes
value 4891346238
```

- Obtain per-device XFS metrics with **pminfo**:

```
# pminfo --fetch --online xfs.perdev.read xfs.perdev.write

xfs.perdev.read [number of XFS file system read operations]
inst [0 or "loop1"] value 0
inst [0 or "loop2"] value 0

xfs.perdev.write [number of XFS file system write operations]
inst [0 or "loop1"] value 86
inst [0 or "loop2"] value 0
```

Additional resources

- **pminfo(1)** man page
- [PCP metric groups for XFS](#)
- [Per-device PCP metric groups for XFS](#)

9.3. RESETTING XFS PERFORMANCE METRICS WITH PMSTORE

With PCP, you can modify the values of certain metrics, especially if the metric acts as a control variable, such as the **xfs.control.reset** metric. To modify a metric value, use the **pmstore** tool.

This procedure describes how to reset XFS metrics using the **pmstore** tool.

Prerequisites

- PCP is installed. For more information, see [Installing and enabling PCP](#).

Procedure

1. Display the value of a metric:

```
$ pminfo -f xfs.write
xfs.write
value 325262
```

2. Reset all the XFS metrics:

```
# pmstore xfs.control.reset 1
xfs.control.reset old value=0 new value=1
```

Verification steps

- View the information after resetting the metric:

```
$ pminfo --fetch xfs.write
xfs.write
value 0
```

Additional resources

- **pmstore(1)** and **pminfo(1)** man pages
- [Tools distributed with PCP](#)
- [PCP metric groups for XFS](#)

9.4. PCP METRIC GROUPS FOR XFS

The following table describes the available PCP metric groups for XFS.

Table 9.1. Metric groups for XFS

Metric Group	Metrics provided
xfs.*	General XFS metrics including the read and write operation counts, read and write byte counts. Along with counters for the number of times inodes are flushed, clustered and number of failure to cluster.
xfs.allocs.* xfs.alloc_btree.*	Range of metrics regarding the allocation of objects in the file system, these include number of extent and block creations/frees. Allocation tree lookup and compares along with extend record creation and deletion from the btree.
xfs.block_map.* xfs.bmap_btree.*	Metrics include the number of block map read/write and block deletions, extent list operations for insertion, deletions and lookups. Also operations counters for compares, lookups, insertions and deletion operations from the blockmap.
xfs.dir_ops.*	Counters for directory operations on XFS file systems for creation, entry deletions, count of "getdent" operations.
xfs.transactions.*	Counters for the number of meta-data transactions, these include the count for the number of synchronous and asynchronous transactions along with the number of empty transactions.
xfs.inode_ops.*	Counters for the number of times that the operating system looked for an XFS inode in the inode cache with different outcomes. These count cache hits, cache misses, and so on.
xfs.log.* xfs.log_tail.*	Counters for the number of log buffer writes over XFS file systems includes the number of blocks written to disk. Metrics also for the number of log flushes and pinning.
xfs.xstrat.*	Counts for the number of bytes of file data flushed out by the XFS flush daemon along with counters for number of buffers flushed to contiguous and non-contiguous space on disk.
xfs.attr.*	Counts for the number of attribute get, set, remove and list operations over all XFS file systems.
xfs.quota.*	Metrics for quota operation over XFS file systems, these include counters for number of quota reclaims, quota cache misses, cache hits and quota data reclaims.

xfs.buffer.*	Range of metrics regarding XFS buffer objects. Counters include the number of requested buffer calls, successful buffer locks, waited buffer locks, miss_locks, miss_retries and buffer hits when looking up pages.
xfs.btree.*	Metrics regarding the operations of the XFS btree.
xfs.control.reset	Configuration metrics which are used to reset the metric counters for the XFS stats. Control metrics are toggled by means of the pmstore tool.

9.5. PER-DEVICE PCP METRIC GROUPS FOR XFS

The following table describes the available per-device PCP metric group for XFS.

Table 9.2. Per-device PCP metric groups for XFS

Metric Group	Metrics provided
xfs.perdev.*	General XFS metrics including the read and write operation counts, read and write byte counts. Along with counters for the number of times inodes are flushed, clustered and number of failure to cluster.
xfs.perdev.allocs.* xfs.perdev.alloc_btree.*	Range of metrics regarding the allocation of objects in the file system, these include number of extent and block creations/frees. Allocation tree lookup and compares along with extend record creation and deletion from the btree.
xfs.perdev.block_map.* xfs.perdev.bmap_btree.*	Metrics include the number of block map read/write and block deletions, extent list operations for insertion, deletions and lookups. Also operations counters for compares, lookups, insertions and deletion operations from the blockmap.
xfs.perdev.dir_ops.*	Counters for directory operations of XFS file systems for creation, entry deletions, count of “getdent” operations.
xfs.perdev.transactions.*	Counters for the number of meta-data transactions, these include the count for the number of synchronous and asynchronous transactions along with the number of empty transactions.
xfs.perdev.inode_ops.*	Counters for the number of times that the operating system looked for an XFS inode in the inode cache with different outcomes. These count cache hits, cache misses, and so on.

xfs.perdev.log.* xfs.perdev.log_tail.*	Counters for the number of log buffer writes over XFS filesystems includes the number of blocks written to disk. Metrics also for the number of log flushes and pinning.
xfs.perdev.xstrat.*	Counts for the number of bytes of file data flushed out by the XFS flush daemon along with counters for number of buffers flushed to contiguous and non-contiguous space on disk.
xfs.perdev.attr.*	Counts for the number of attribute get, set, remove and list operations over all XFS file systems.
xfs.perdev.quota.*	Metrics for quota operation over XFS file systems, these include counters for number of quota reclaims, quota cache misses, cache hits and quota data reclaims.
xfs.perdev.buffer.*	Range of metrics regarding XFS buffer objects. Counters include the number of requested buffer calls, successful buffer locks, waited buffer locks, miss_locks, miss_retries and buffer hits when looking up pages.
xfs.perdev.btree.*	Metrics regarding the operations of the XFS btree.

CHAPTER 10. SETTING UP GRAPHICAL REPRESENTATION OF PCP METRICS

Using a combination of **pcp**, **grafana**, **pcp redis**, **pcp bpfftrace**, and **pcp vector** provides graphs, based on the live data or data collected by Performance Co-Pilot (PCP).

This section describes how to set up and access the graphical representation of PCP metrics.

10.1. SETTING UP PCP WITH PCP-ZEROCONF

This procedure describes how to set up PCP on a system with the **pcp-zeroconf** package. Once the **pcp-zeroconf** package is installed, the system records the default set of metrics into archived files.

Procedure

- Install the **pcp-zeroconf** package:

```
# yum install pcp-zeroconf
```

Verification steps

- Ensure that the **pmlogger** service is active, and starts archiving the metrics:

```
# pcp | grep pmlogger
pmlogger: primary logger: /var/log/pcp/pmlogger/localhost.localdomain/20200401.00.12
```

Additional resources

- **pmlogger** man page
- [Monitoring performance with Performance Co-Pilot](#)

10.2. SETTING UP A GRAFANA-SERVER

Grafana generates graphs that are accessible from a browser. The **grafana-server** is a back-end server for the Grafana dashboard. It listens, by default, on all interfaces, and provides web services accessed through the web browser. The **grafana-pcp** plugin interacts with the **pmproxy** protocol in the backend.

This procedure describes how to set up a **grafana-server**.

Prerequisites

- PCP is configured. For more information, see [Setting up PCP with pcp-zeroconf](#).

Procedure

1. Install the following packages:

```
# yum install grafana grafana-pcp
```

2. Restart and enable the following service:

```
# systemctl restart grafana-server
# systemctl enable grafana-server
```

Verification steps

- Ensure that the **grafana-server** is listening and responding to requests:

```
# ss -ntlp | grep 3000
LISTEN 0 128 *:3000 *.* users:(("grafana-server",pid=19522,fd=7))
```

- Ensure that the **grafana-pcp** plugin is installed:

```
# grafana-cli plugins ls | grep performancecopilot-pcp-app
performancecopilot-pcp-app @ 3.1.0
```

Additional resources

- **pmproxy(1)** and **grafana-server** man pages

10.3. ACCESSING THE GRAFANA WEB UI

This procedure describes how to access the Grafana web interface.

Using the Grafana web interface, you can:

- add PCP Redis, PCP bpftrace, and PCP Vector data sources
- create dashboard
- view an overview of any useful metrics
- create alerts in PCP Redis

Prerequisites

1. PCP is configured. For more information, see [Setting up PCP with pcp-zeroconf](#).
2. The **grafana-server** is configured. For more information, see [Setting up a grafana-server](#).

Procedure

1. On the client system, open a browser and access the **grafana-server** on port **3000**, using `http://192.0.2.0:3000` link.
Replace `192.0.2.0` with your machine IP.
2. For the first login, enter **admin** in both the **Email or username** and **Password** field.
Grafana prompts to set a **New password** to create a secured account. If you want to set it later, click **Skip**.

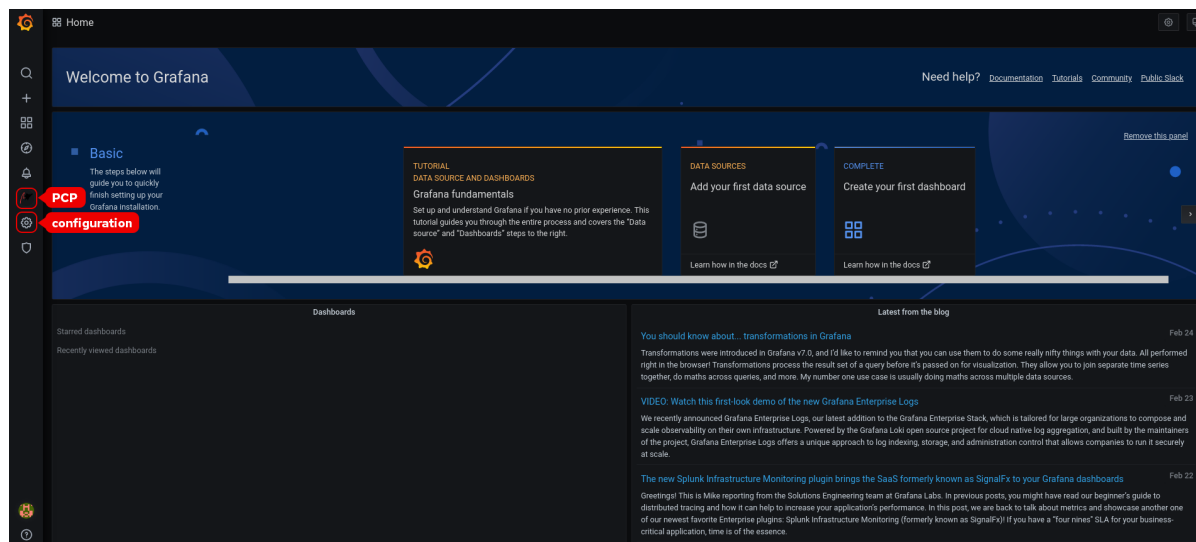

3. From the menu, hover over the  **Configuration** icon and then click **Plugins**.

4. In the **Plugins** tab, type performance co-pilot in the **Search by name or type** text box and then click **Performance Co-Pilot (PCP)** plugin.
5. In the **Plugins / Performance Co-Pilot** pane, click **Enable**.

6. Click Grafana icon. The Grafana **Home** page is displayed.

Figure 10.1. Home Dashboard

**NOTE**

The top corner of the screen has a similar  icon, but it controls the general **Dashboard settings**.

7. In the Grafana **Home** page, click **Add your first data source** to add PCP Redis, PCP bpfftrace, and PCP Vector data sources. For more information on adding data source, see:
 - To add pcp redis data source, view default dashboard, create a panel, and an alert rule, see [Creating panels and alert in PCP Redis data source](#).
 - To add pcp bpfftrace data source and view the default dashboard, see [Viewing the PCP bpfftrace System Analysis dashboard](#).
 - To add pcp vector data source, view the default dashboard, and to view the vector checklist, see [Viewing the PCP Vector Checklist](#).

8. Optional: From the menu, hover over the **admin** profile icon to change the **Preferences** including **Edit Profile**, **Change Password**, or to **Sign out**.

Additional resources

- **grafana-cli** and **grafana-server** man pages

10.4. CONFIGURING PCP REDIS

This section provides information for configuring PCP Redis data source.

Use the PCP Redis data source to:

- View data archives
- Query time series using `pmseries` language
- Analyze data across multiple hosts

Prerequisites

1. PCP is configured. For more information, see [Setting up PCP with `pcp-zeroconf`](#).
2. The **grafana-server** is configured. For more information, see [Setting up a grafana-server](#).

Procedure

1. Install the **redis** package:

```
# yum install redis
```

2. Start and enable the following services:

```
# systemctl start pmproxy redis
# systemctl enable pmproxy redis
```

3. Mail transfer agent, for example, **sendmail** or **postfix** is installed and configured.
4. Ensure that the **allow_loading_unsigned_plugins** parameter is set to PCP Redis database in the **grafana.ini** file:

```
# vi /etc/grafana/grafana.ini

allow_loading_unsigned_plugins = pcp-redis-datasource
```

5. Restart the **grafana-server**:

```
# systemctl restart grafana-server
```

Verification steps

- Ensure that the **pmproxy** and **redis** are working:

```
# pmseries disk.dev.read
2eb3e58d8f1e231361fb15cf1aa26fe534b4d9df
```

This command does not return any data if the **redis** package is not installed.

Additional resources

- **pmseries(1)** man page

10.5. CREATING PANELS AND ALERT IN PCP REDIS DATA SOURCE

After adding the PCP Redis data source, you can view the dashboard with an overview of useful metrics, add a query to visualize the load graph, and create alerts that help you to view the system issues after they occur.

Prerequisites

1. The PCP Redis is configured. For more information, see [Configuring PCP Redis](#).
2. The **grafana-server** is accessible. For more information, see [Accessing the Grafana web UI](#).

Procedure

1. Log into the Grafana web UI.
2. In the Grafana **Home** page, click **Add your first data source**
3. In the **Add data source** pane, type **redis** in the **Filter by name or type** text box and then click **PCP Redis**.
4. In the **Data Sources / PCP Redis** pane, perform the following:
 - a. Add **http://localhost:44322** in the **URL** field and then click **Save & Test**.
 - b. Click **Dashboards tab** → **Import** → **PCP Redis: Host Overview** to see a dashboard with an overview of any useful metrics.

Figure 10.2. PCP Redis: Host Overview

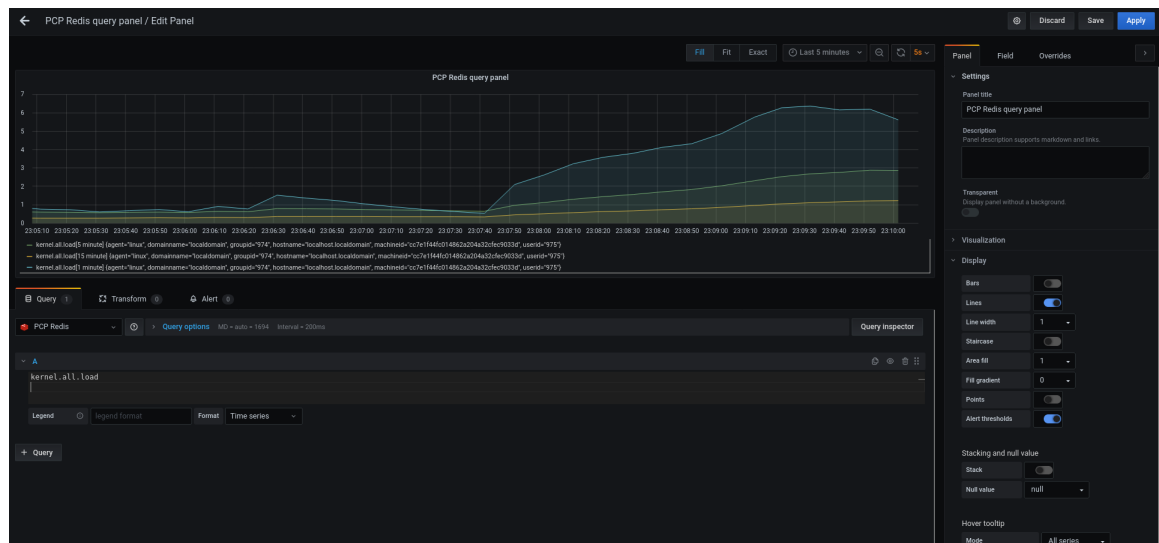

5. Add a new panel:

- a. From the menu, hover over the **icon** to add a panel. **Create icon → Dashboard → Add new panel**
- b. In the **Query** tab, select the **PCP Redis** from the query list instead of the selected **default** option and in the text field of **A**, enter metric, for example, **kernel.all.load** to visualize the kernel load graph.

- c. Optional: Add **Panel title** and **Description**, and update other options from the **Settings**.
- d. Click **Save** to apply changes and save the dashboard. Add **Dashboard name**.
- e. Click **Apply** to apply changes and go back to the dashboard.

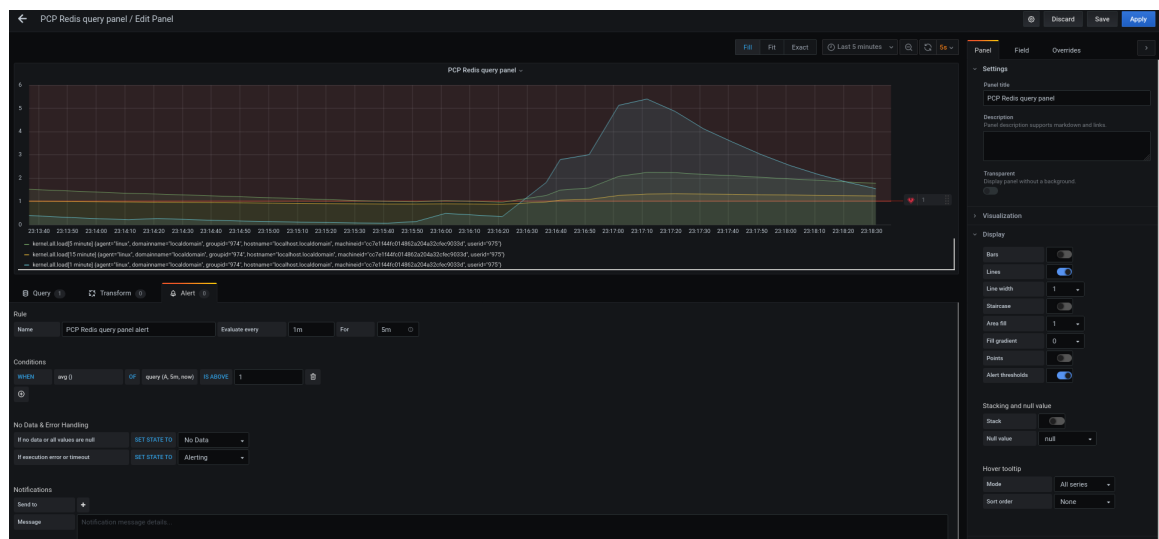

Figure 10.3. PCP Redis query panel

6. Create an alert rule:

- a. In the **PCP Redis query panel**, click **Alert** and then click **Create Alert**.
- b. Edit the **Name**, **Evaluate query**, and **For** fields from the **Rule**, and specify the **Conditions** for your alert.
- c. Click **Save** to apply changes and save the dashboard. Click **Apply** to apply changes and go back to the dashboard.

Figure 10.4. Creating alerts in the PCP Redis panel

- d. Optional: In the same panel, scroll down and click **Delete** icon to delete the created rule.

- e. Optional: From the menu, click **Alerting** icon to view the created alert rules with different alert statuses, to edit the alert rule, or to pause the existing rule from the **Alert Rules** tab.

To add a notification channel for the created alert rule to receive an alert notification from Grafana, see [Adding notification channels for alerts](#).

10.6. ADDING NOTIFICATION CHANNELS FOR ALERTS

By adding notification channels, you can receive an alert notification from Grafana whenever the alert rule conditions are met and the system needs further monitoring.

You can receive these alerts after selecting any one type from the supported list of notifiers, which includes **DingDing**, **Discord**, **Email**, **Google Hangouts Chat**, **HipChat**, **Kafka REST Proxy**, **LINE**, **Microsoft Teams**, **OpsGenie**, **PagerDuty**, **Prometheus Alertmanager**, **Pushover**, **Sensu**, **Slack**, **Telegram**, **Threema Gateway**, **VictorOps**, and **webhook**.

Prerequisites

1. The **grafana-server** is accessible. For more information, see [Accessing the Grafana web UI](#).
2. An alert rule is created. For more information, see [Creating panels and alert in PCP Redis data source](#).
3. Configure SMTP and add a valid sender's email address in the **grafana/grafana.ini** file:

```
# vi /etc/grafana/grafana.ini

[smtp]
enabled = true
from_address = abc@gmail.com
```

Replace *abc@gmail.com* by a valid email address.

Procedure

1. From the menu, hover over the **Alerting** icon → click **Notification channels** → **Add channel**.
2. In the Add notification channel details pane, perform the following:
 - a. Enter your name in the **Name** text box
 - b. Select the communication **Type**, for example, Email and enter the email address. You can add multiple email addresses using the ; separator.
 - c. Optional: Configure **Optional Email settings** and **Notification settings**.
3. Click **Save**.
4. Select a notification channel in the alert rule:

- a. From the menu, hover over the **Alerting** icon and then click **Alert rules**.

- b. From the **Alert Rules** tab, click the created alert rule.
- c. On the **Notifications** tab, select your notification channel name from the **Send to** option, and then add an alert message.
- d. Click **Apply**.

Additional resources

- [Upstream Grafana documentation for alert notifications](#)

10.7. SETTING UP AUTHENTICATION BETWEEN PCP COMPONENTS

You can setup authentication using the **scram-sha-256** authentication mechanism, which is supported by PCP through the Simple Authentication Security Layer (SASL) framework.

NOTE

From Red Hat Enterprise Linux 8.3, PCP supports the **scram-sha-256** authentication mechanism.

Procedure

1. Install the **sasl** framework for the **scram-sha-256** authentication mechanism:

```
# yum install cyrus-sasl-scram cyrus-sasl-lib
```

2. Specify the supported authentication mechanism and the user database path in the **pmcd.conf** file:

```
# vi /etc/sasl2/pmcd.conf

mech_list: scram-sha-256

sasldb_path: /etc/pcp/passwd.db
```

3. Create a new user:

```
# useradd -r metrics
```

Replace *metrics* by your user name.

4. Add the created user in the user database:

```
# saslpasswd2 -a pmcd metrics

Password:
Again (for verification):
```

To add the created user, you are required to enter the *metrics* account password.

5. Set the permissions of the user database:

```
# chown root:pcp /etc/pcp/passwd.db
# chmod 640 /etc/pcp/passwd.db
```

6. Restart the **pmcd** service:

```
# systemctl restart pmcd
```

Verification steps

- Verify the **sasl** configuration:

```
# pminfo -f -h "pcp://127.0.0.1?username=metrics" disk.dev.read
Password:
disk.dev.read
inst [0 or "sda"] value 19540
```

Additional resources

- **saslauthd(8)**, **pminfo(1)**, and **sha256** man pages
- [How can I setup authentication between PCP components, like PMDAs and pmcd in RHEL 8.2?](#)

10.8. INSTALLING PCP BPFTRACE

Install the PCP **bpfftrace** agent to introspect a system and to gather metrics from the kernel and user-space tracepoints.

The **bpfftrace** agent uses bpfftrace scripts to gather the metrics. The **bpfftrace** scripts use the enhanced Berkeley Packet Filter (**eBPF**).

This procedure describes how to install a **pcp bpfftrace**.

Prerequisites

1. PCP is configured. For more information, see [Setting up PCP with pcp-zeroconf](#).
2. The **grafana-server** is configured. For more information, see [Setting up a grafana-server](#).
3. The **scram-sha-256** authentication mechanism is configured. For more information, see [Setting up authentication between PCP components](#).

Procedure

1. Install the **pcp-pmda-bpfftrace** package:

```
# yum install pcp-pmda-bpfftrace
```

2. Edit the **bpfftrace.conf** file and add the user that you have created in the {setting-up-authentication-between-pcp-components}:

```
# vi /var/lib/pcp/pmdas/bpfftrace/bpfftrace.conf

[dynamic_scripts]
```

```
enabled = true
auth_enabled = true
allowed_users = root,metrics
```

Replace *metrics* by your user name.

3. Install **bpfftrace** PMDA:

```
# cd /var/lib/pcp/pmdas/bpfftrace/
# ./Install
Updating the Performance Metrics Name Space (PMNS) ...
Terminate PMDA if already installed ...
Updating the PMCD control file, and notifying PMCD ...
Check bpfftrace metrics have appeared ... 7 metrics and 6 values
```

The **pmda-bpfftrace** is now installed, and can only be used after authenticating your user. For more information, see [Viewing the PCP bpfftrace System Analysis dashboard](#).

Additional resources

- **pmdabpfftrace(1)** and **bpfftrace** man pages

10.9. VIEWING THE PCP BPFTRACE SYSTEM ANALYSIS DASHBOARD

Using the PCP bpfftrace data source, you can access the live data from sources which are not available as normal data from the **pmlogger** or archives

In the PCP bpfftrace data source, you can view the dashboard with an overview of useful metrics.

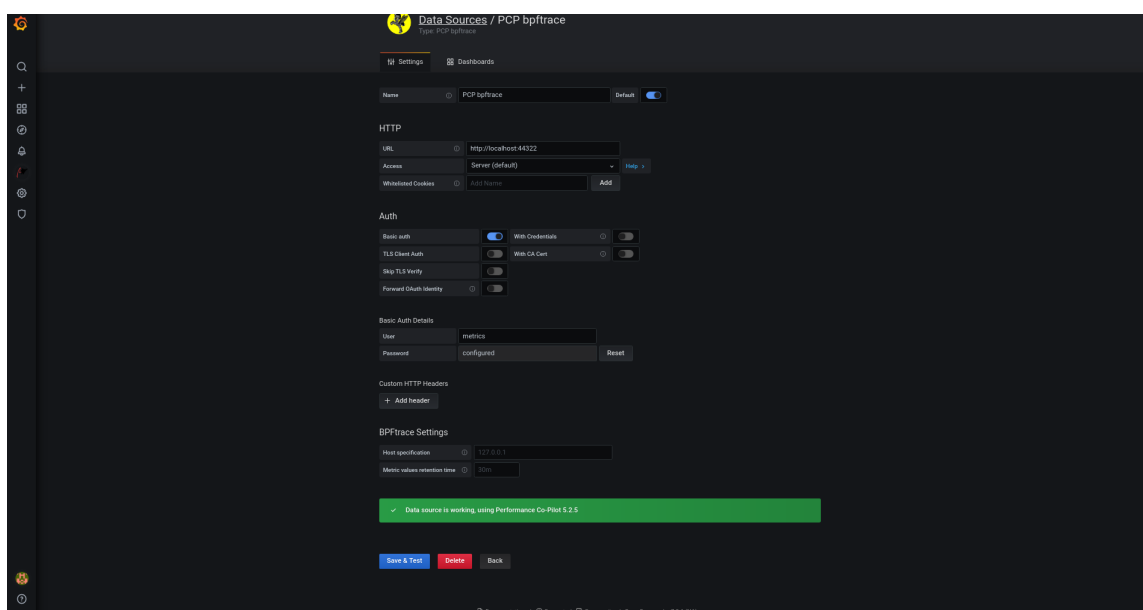

Prerequisites

1. The PCP bpfftrace is installed. For more information, see [Installing PCP bpfftrace](#).
2. The **grafana-server** is accessible. For more information, see [Accessing the Grafana web UI](#).

Procedure

1. Log into the Grafana web UI.
2. In the Grafana **Home** page, click **Add your first data source**
3. In the **Add data source** pane, type bpfftrace in the **Filter by name or type** text box and then click **PCP bpfftrace**.
4. In the **Data Sources / PCP bpfftrace** pane, perform the following:
 - a. Add **http://localhost:44322** in the **URL** field.
 - b. Toggle the **Basic Auth** option and add the created user credentials in the **User** and **Password** field.
 - c. Click **Save & Test**.

Figure 10.5. Adding PCP bpfftrace in the data source

- d. Click **Dashboards** tab → **Import** → **PCP bpfftrace: System Analysis** to see a dashboard with an overview of any useful metrics.

Figure 10.6. PCP bpfftrace: System Analysis

10.10. INSTALLING PCP VECTOR

This procedure describes how to install a **pcp vector**.

Prerequisites

1. PCP is configured. For more information, see [Setting up PCP with pcp-zeroconf](#).
2. The **grafana-server** is configured. For more information, see [Setting up a grafana-server](#).

Procedure

1. Install the **pcp-pmda-bcc** package:

```
# yum install pcp-pmda-bcc
```

2. Install the **bcc** PMDA:

```
# cd /var/lib/pcp/pmdas/bcc
# ./Install
[Wed Apr 1 00:27:48] pmdabcc(22341) Info: Initializing, currently in 'notready' state.
[Wed Apr 1 00:27:48] pmdabcc(22341) Info: Enabled modules:
[Wed Apr 1 00:27:48] pmdabcc(22341) Info: ['biolatency', 'sysfork',
[...]]
Updating the Performance Metrics Name Space (PMNS) ...
Terminate PMDA if already installed ...
Updating the PMCD control file, and notifying PMCD ...
Check bcc metrics have appeared ... 1 warnings, 1 metrics and 0 values
```

Additional resources

- **pmdabcc(1)** man page

10.11. VIEWING THE PCP VECTOR CHECKLIST

The PCP Vector data source displays live metrics and uses the **pcp** metrics. It analyzes data for individual hosts.

After adding the PCP Vector data source, you can view the dashboard with an overview of useful metrics and view the related troubleshooting or reference links in the checklist.

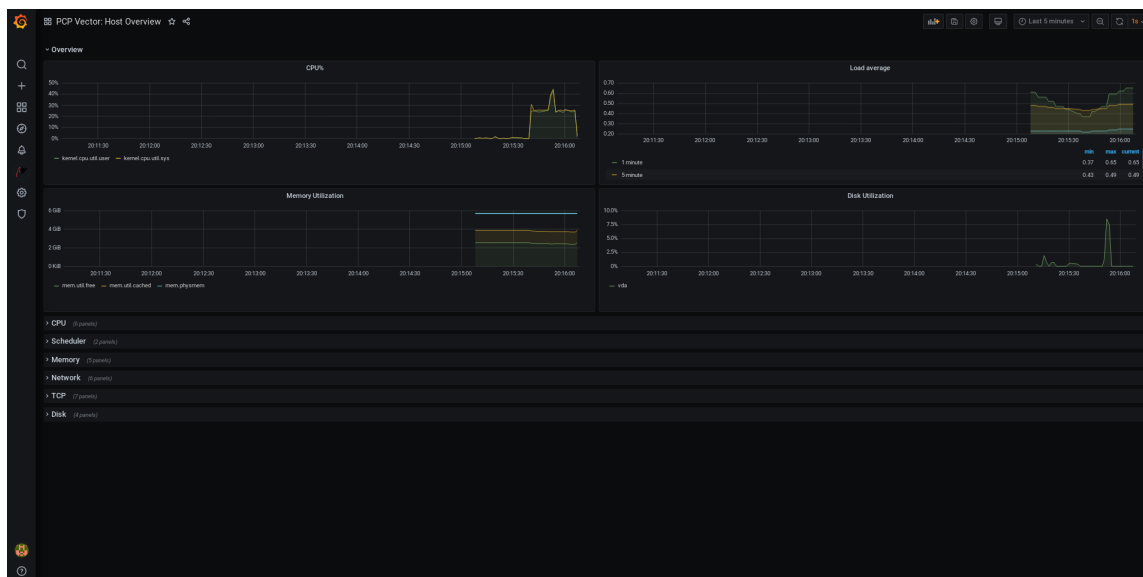

Prerequisites

1. The PCP Vector is installed. For more information, see [Installing PCP Vector](#).
2. The **grafana-server** is accessible. For more information, see [Accessing the Grafana web UI](#).

Procedure

1. Log into the Grafana web UI.
2. In the Grafana **Home** page, click **Add your first data source**
3. In the **Add data source** pane, type vector in the **Filter by name or type** text box and then click **PCP Vector**.
4. In the **Data Sources / PCP Vector** pane, perform the following:
 - a. Add **http://localhost:44322** in the **URL** field and then click **Save & Test**.
 - b. Click **Dashboards tab** → **Import** → **PCP Vector: Host Overview** to see a dashboard with an overview of any useful metrics.

Figure 10.7. PCP Vector: Host Overview

5. From the menu, hover over the

Performance Co-Pilot plugin and then click **PCP**

Vector Checklist.

In the PCP checklist, click

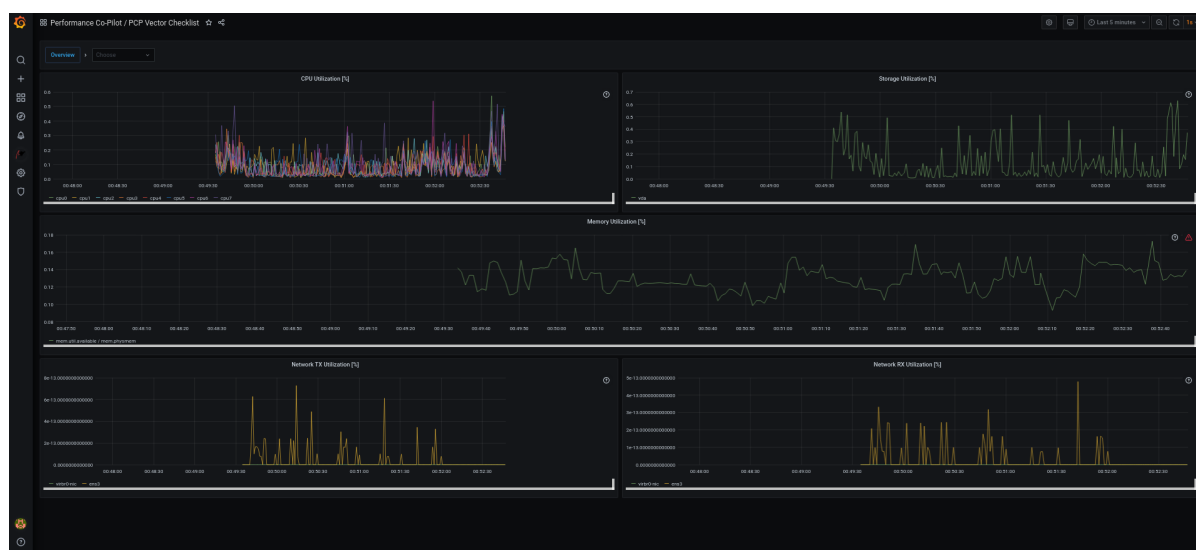

help or

warning icon to view the related troubleshooting or reference links.

Figure 10.8. Performance Co-Pilot / PCP Vector Checklist

10.12. TROUBLESHOOTING GRAFANA ISSUES

This section describes how to troubleshoot Grafana issues, such as, Grafana does not display any data, the dashboard is black, or similar issues.

Procedure

- Verify that the **pmlogger** service is up and running by executing the following command:

```
$ systemctl status pmlogger
```

- Verify if files were created or modified to the disk by executing the following command:

```
$ ls /var/log/pcp/pmlogger/${hostname}/ -rtl
total 4024
-rw-r--r--. 1 pcp pcp 45996 Oct 13 2019 20191013.20.07.meta.xz
-rw-r--r--. 1 pcp pcp 412 Oct 13 2019 20191013.20.07.index
-rw-r--r--. 1 pcp pcp 32188 Oct 13 2019 20191013.20.07.0.xz
-rw-r--r--. 1 pcp pcp 44756 Oct 13 2019 20191013.20.30-00.meta.xz
[..]
```

- Verify that the **pmproxy** service is running by executing the following command:

```
$ systemctl status pmproxy
```

- Verify that **pmproxy** is running, time series support is enabled, and a connection to Redis is established by viewing the **/var/log/pcp/pmproxy/pmproxy.log** file and ensure that it contains the following text:

```
pmproxy(1716) Info: Redis slots, command keys, schema version setup
```

Here, **1716** is the PID of pmproxy, which will be different for every invocation of **pmproxy**.

- Verify if the Redis database contains any keys by executing the following command:

```
$ redis-cli dbsize
(integer) 34837
```

- Verify if any PCP metrics are in the Redis database and **pmproxy** is able to access them by executing the following commands:

```
$ pmseries disk.dev.read
2eb3e58d8f1e231361fb15cf1aa26fe534b4d9df

$ pmseries "disk.dev.read[count:10]"
2eb3e58d8f1e231361fb15cf1aa26fe534b4d9df
[Mon Jul 26 12:21:10.085468000 2021] 117971
70e83e88d4e1857a3a31605c6d1333755f2dd17c
[Mon Jul 26 12:21:00.087401000 2021] 117758
70e83e88d4e1857a3a31605c6d1333755f2dd17c

CHAPTER 11. OPTIMIZING THE SYSTEM PERFORMANCE USING THE WEB CONSOLE

Learn how to set a performance profile in the RHEL 8 web console to optimize the performance of the system for a selected task.

11.1. PERFORMANCE TUNING OPTIONS IN THE WEB CONSOLE

Red Hat Enterprise Linux 8 provides several performance profiles that optimize the system for the following tasks:

- Systems using the desktop
- Throughput performance
- Latency performance
- Network performance
- Low power consumption
- Virtual machines

The **tuned** service optimizes system options to match the selected profile.

In the web console, you can set which performance profile your system uses.

Additional resources

- [Getting started with TuneD](#)

11.2. SETTING A PERFORMANCE PROFILE IN THE WEB CONSOLE

This procedure uses the web console to optimize the system performance for a selected task.

Prerequisites

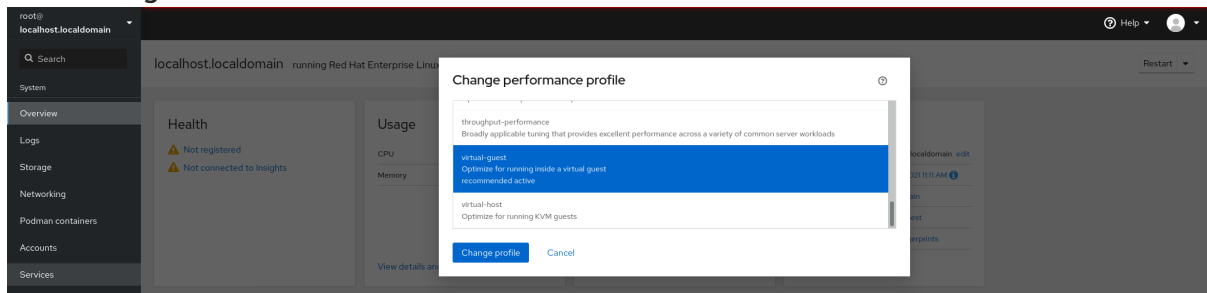

- Make sure the web console is installed and accessible. For details, see [Installing the web console](#).

Procedure

1. Log into the RHEL 8 web console. For details, see [Logging in to the web console](#).
2. Click **Overview**.
3. In the **Performance Profile** field, click the current performance profile.

4. In the **Change Performance Profile** dialog box, change the profile if necessary.
5. Click **Change Profile**.

Verification steps

- The **Overview** tab now shows the selected performance profile.

11.3. MONITORING PERFORMANCE USING THE WEB CONSOLE

Red Hat's web console uses the Utilization Saturation and Errors (USE) Method for troubleshooting. The new performance metrics page has a historical view of your data organized chronologically with the newest data at the top.

Here, you can view the events, errors, and graphical representation for resource utilization and saturation.

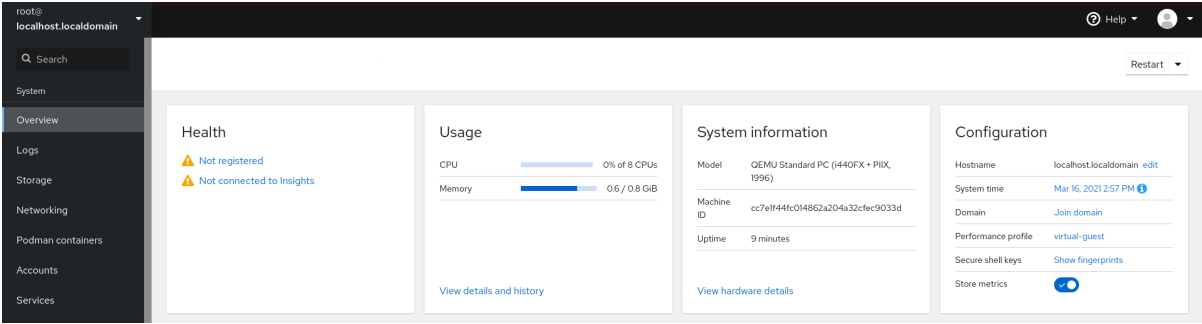

Prerequisites

1. Make sure the web console is installed and accessible. For details, see [Installing the web console](#).
2. Install the **cockpit-pcp** package, which enables collecting the performance metrics:

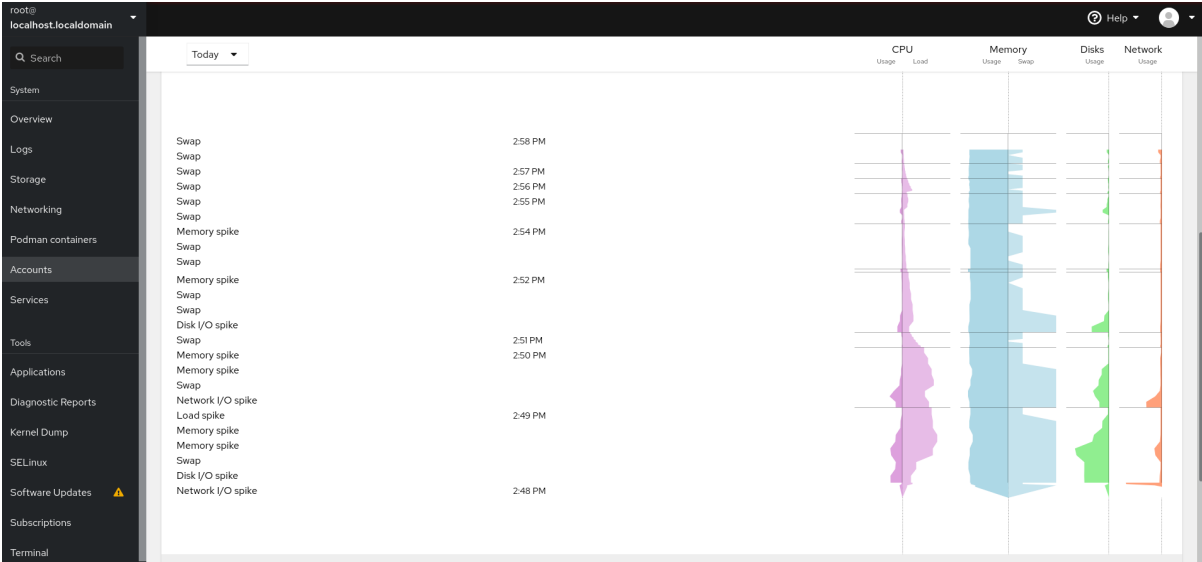

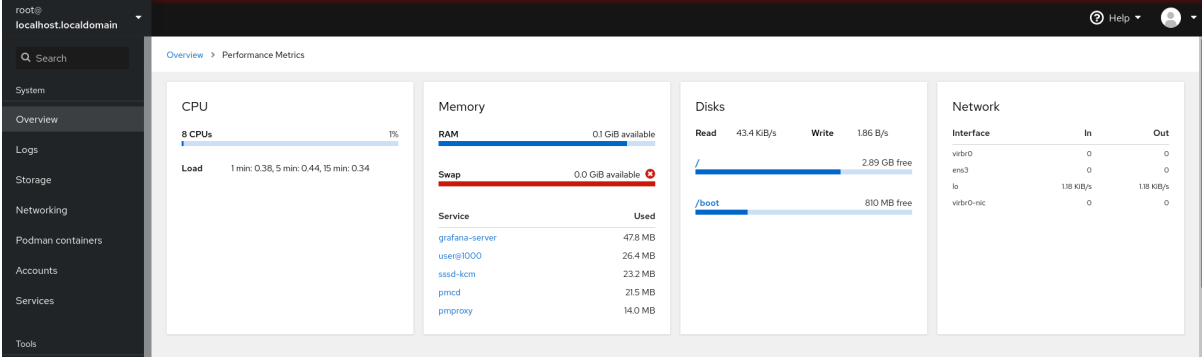

```
# yum install cockpit-pcp
```

Procedure

1. Log into the RHEL 8 web console. For details, see [Logging in to the web console](#).
2. Click **Overview**.

3. Click **View details and history** to view the **Performance Metrics**.

CHAPTER 12. SETTING THE DISK SCHEDULER

The disk scheduler is responsible for ordering the I/O requests submitted to a storage device.

You can configure the scheduler in several different ways:

- Set the scheduler using **TuneD**, as described in [Setting the disk scheduler using TuneD](#)
- Set the scheduler using **udev**, as described in [Setting the disk scheduler using udev rules](#)
- Temporarily change the scheduler on a running system, as described in [Temporarily setting a scheduler for a specific disk](#)

NOTE

In Red Hat Enterprise Linux 8, block devices support only multi-queue scheduling. This enables the block layer performance to scale well with fast solid-state drives (SSDs) and multi-core systems.

The traditional, single-queue schedulers, which were available in Red Hat Enterprise Linux 7 and earlier versions, have been removed.

12.1. AVAILABLE DISK SCHEDULERS

The following multi-queue disk schedulers are supported in Red Hat Enterprise Linux 8:

none

Implements a first-in first-out (FIFO) scheduling algorithm. It merges requests at the generic block layer through a simple last-hit cache.

mq-deadline

Attempts to provide a guaranteed latency for requests from the point at which requests reach the scheduler.

The **mq-deadline** scheduler sorts queued I/O requests into a read or write batch and then schedules them for execution in increasing logical block addressing (LBA) order. By default, read batches take precedence over write batches, because applications are more likely to block on read I/O operations. After **mq-deadline** processes a batch, it checks how long write operations have been starved of processor time and schedules the next read or write batch as appropriate.

This scheduler is suitable for most use cases, but particularly those in which the write operations are mostly asynchronous.

bfq

Targets desktop systems and interactive tasks.

The **bfq** scheduler ensures that a single application is never using all of the bandwidth. In effect, the storage device is always as responsive as if it was idle. In its default configuration, **bfq** focuses on delivering the lowest latency rather than achieving the maximum throughput.

bfq is based on **cfq** code. It does not grant the disk to each process for a fixed time slice but assigns a *budget* measured in number of sectors to the process.

This scheduler is suitable while copying large files and the system does not become unresponsive in this case.

kyber

The scheduler tunes itself to achieve a latency goal by calculating the latencies of every I/O request submitted to the block I/O layer. You can configure the target latencies for read, in the case of cache-misses, and synchronous write requests.

This scheduler is suitable for fast devices, for example NVMe, SSD, or other low latency devices.

12.2. DIFFERENT DISK SCHEDULERS FOR DIFFERENT USE CASES

Depending on the task that your system performs, the following disk schedulers are recommended as a baseline prior to any analysis and tuning tasks:

Table 12.1. Disk schedulers for different use cases

Use case	Disk scheduler
Traditional HDD with a SCSI interface	Use mq-deadline or bfq .
High-performance SSD or a CPU-bound system with fast storage	Use none , especially when running enterprise applications. Alternatively, use kyber .
Desktop or interactive tasks	Use bfq .
Virtual guest	Use mq-deadline . With a host bus adapter (HBA) driver that is multi-queue capable, use none .

12.3. THE DEFAULT DISK SCHEDULER

Block devices use the default disk scheduler unless you specify another scheduler.

NOTE

For **non-volatile Memory Express (NVMe)** block devices specifically, the default scheduler is **none** and Red Hat recommends not changing this.

The kernel selects a default disk scheduler based on the type of device. The automatically selected scheduler is typically the optimal setting. If you require a different scheduler, Red Hat recommends to use **udev** rules or the **TuneD** application to configure it. Match the selected devices and switch the scheduler only for those devices.

12.4. DETERMINING THE ACTIVE DISK SCHEDULER

This procedure determines which disk scheduler is currently active on a given block device.

Procedure

- Read the content of the **/sys/block/device/queue/scheduler** file:

```
# cat /sys/block/device/queue/scheduler
```

```
[mq-deadline] kyber bfq none
```

■

In the file name, replace *device* with the block device name, for example **sdc**.

The active scheduler is listed in square brackets (**[]**).

12.5. SETTING THE DISK SCHEDULER USING TUNED

This procedure creates and enables a **TuneD** profile that sets a given disk scheduler for selected block devices. The setting persists across system reboots.

In the following commands and configuration, replace:

- *device* with the name of the block device, for example **sdf**
- *selected-scheduler* with the disk scheduler that you want to set for the device, for example **bfq**

Prerequisites

- The **tuned** service is installed and enabled. For details, see [Installing and enabling TuneD](#).

Procedure

1. Optional: Select an existing **TuneD** profile on which your profile will be based. For a list of available profiles, see [TuneD profiles distributed with RHEL](#).
To see which profile is currently active, use:

```
$ tuned-adm active
```

2. Create a new directory to hold your **TuneD** profile:

```
# mkdir /etc/tuned/my-profile
```

3. Find the system unique identifier of the selected block device:

```
$ udevadm info --query=property --name=/dev/device | grep -E '(WWN|SERIAL)'
```

```
ID_WWN=0x5002538d00000000_
ID_SERIAL=Generic-SD_MMC_20120501030900000-0:0
ID_SERIAL_SHORT=20120501030900000
```

NOTE

The command in this example will return all values identified as a World Wide Name (WWN) or serial number associated with the specified block device. Although it is preferred to use a WWN, the WWN is not always available for a given device and any values returned by the example command are acceptable to use as the *device system unique ID*.

4. Create the **/etc/tuned/my-profile/tuned.conf** configuration file. In the file, set the following options:
 - a. Optional: Include an existing profile:

```
[main]
include=existing-profile
```

- b. Set the selected disk scheduler for the device that matches the WWN identifier:

```
[disk]
devices_udev_regex=IDNAME=device system unique id
elevator=selected-scheduler
```

Here:

- Replace *IDNAME* with the name of the identifier being used (for example, **ID_WWN**).
- Replace *device system unique id* with the value of the chosen identifier (for example, **0x5002538d00000000**).
To match multiple devices in the **devices_udev_regex** option, enclose the identifiers in parentheses and separate them with vertical bars:

```
devices_udev_regex=(ID_WWN=0x5002538d00000000)|
(ID_WWN=0x1234567800000000)
```

5. Enable your profile:

```
# tuned-adm profile my-profile
```

Verification steps

- Verify that the TuneD profile is active and applied:

```
$ tuned-adm active
```

```
Current active profile: my-profile
```

```
$ tuned-adm verify
```

```
Verification succeeded, current system settings match the preset profile.
See tuned log file ('/var/log/tuned/tuned.log') for details.
```

Additional resources

- [Customizing TuneD profiles](#)

12.6. SETTING THE DISK SCHEDULER USING UDEV RULES

This procedure sets a given disk scheduler for specific block devices using **udev** rules. The setting persists across system reboots.

In the following commands and configuration, replace:

- *device* with the name of the block device, for example **sdf**
- *selected-scheduler* with the disk scheduler that you want to set for the device, for example **bfq**

Procedure

1. Find the system unique identifier of the block device:

```
$ udevadm info --name=/dev/device | grep -E '(WWN|SERIAL)'
E: ID_WWN=0x5002538d00000000
E: ID_SERIAL=Generic_SD_MMC_20120501030900000-0:0
E: ID_SERIAL_SHORT=20120501030900000
```

NOTE

The command in this example will return all values identified as a World Wide Name (WWN) or serial number associated with the specified block device. Although it is preferred to use a WWN, the WWN is not always available for a given device and any values returned by the example command are acceptable to use as the *device system unique ID*.

2. Configure the **udev** rule. Create the **/etc/udev/rules.d/99-scheduler.rules** file with the following content:

```
ACTION=="add|change", SUBSYSTEM=="block", ENV{IDNAME}=="device system unique
id", ATTR{queue/scheduler}="selected-scheduler"
```

Here:

- Replace *IDNAME* with the name of the identifier being used (for example, **ID_WWN**).
- Replace *device system unique id* with the value of the chosen identifier (for example, **0x5002538d00000000**).

3. Reload **udev** rules:

```
# udevadm control --reload-rules
```

4. Apply the scheduler configuration:

```
# udevadm trigger --type=devices --action=change
```

Verification steps

- Verify the active scheduler:

```
# cat /sys/block/device/queue/scheduler
```

12.7. TEMPORARILY SETTING A SCHEDULER FOR A SPECIFIC DISK

This procedure sets a given disk scheduler for specific block devices. The setting does not persist across system reboots.

Procedure

- Write the name of the selected scheduler to the **/sys/block/device/queue/scheduler** file:

■

```
# echo selected-scheduler > /sys/block/device/queue/scheduler
```

In the file name, replace *device* with the block device name, for example **sdc**.

Verification steps

- Verify that the scheduler is active on the device:

```
# cat /sys/block/device/queue/scheduler
```

CHAPTER 13. TUNING THE PERFORMANCE OF A SAMBA SERVER

This chapter describes what settings can improve the performance of Samba in certain situations, and which settings can have a negative performance impact.

Parts of this section were adopted from the [Performance Tuning](#) documentation published in the Samba Wiki. License: [CC BY 4.0](#). Authors and contributors: See the [history](#) tab on the Wiki page.

Prerequisites

- Samba is set up as a file or print server
See [Using Samba as a server](#).

13.1. SETTING THE SMB PROTOCOL VERSION

Each new SMB version adds features and improves the performance of the protocol. The recent Windows and Windows Server operating systems always supports the latest protocol version. If Samba also uses the latest protocol version, Windows clients connecting to Samba benefit from the performance improvements. In Samba, the default value of the server max protocol is set to the latest supported stable SMB protocol version.

NOTE

To always have the latest stable SMB protocol version enabled, do not set the **server max protocol** parameter. If you set the parameter manually, you will need to modify the setting with each new version of the SMB protocol, to have the latest protocol version enabled.

The following procedure explains how to use the default value in the **server max protocol** parameter.

Procedure

1. Remove the **server max protocol** parameter from the **[global]** section in the **/etc/samba/smb.conf** file.
2. Reload the Samba configuration

```
# smbcontrol all reload-config
```

13.2. TUNING SHARES WITH DIRECTORIES THAT CONTAIN A LARGE NUMBER OF FILES

Linux supports case-sensitive file names. For this reason, Samba needs to scan directories for uppercase and lowercase file names when searching or accessing a file. You can configure a share to create new files only in lowercase or uppercase, which improves the performance.

Prerequisites

- Samba is configured as a file server

Procedure

1. Rename all files on the share to lowercase.

NOTE

Using the settings in this procedure, files with names other than in lowercase will no longer be displayed.

2. Set the following parameters in the share's section:

```
case sensitive = true
default case = lower
preserve case = no
short preserve case = no
```

For details about the parameters, see their descriptions in the **smb.conf(5)** man page.

3. Verify the **/etc/samba/smb.conf** file:

```
# testparm
```

4. Reload the Samba configuration:

```
# smbcontrol all reload-config
```

After you applied these settings, the names of all newly created files on this share use lowercase. Because of these settings, Samba no longer needs to scan the directory for uppercase and lowercase, which improves the performance.

13.3. SETTINGS THAT CAN HAVE A NEGATIVE PERFORMANCE IMPACT

By default, the kernel in Red Hat Enterprise Linux is tuned for high network performance. For example, the kernel uses an auto-tuning mechanism for buffer sizes. Setting the **socket options** parameter in the **/etc/samba/smb.conf** file overrides these kernel settings. As a result, setting this parameter decreases the Samba network performance in most cases.

To use the optimized settings from the Kernel, remove the **socket options** parameter from the **[global]** section in the **/etc/samba/smb.conf**.

CHAPTER 14. OPTIMIZING VIRTUAL MACHINE PERFORMANCE

Virtual machines (VMs) always experience some degree of performance deterioration in comparison to the host. The following sections explain the reasons for this deterioration and provide instructions on how to minimize the performance impact of virtualization in RHEL 8, so that your hardware infrastructure resources can be used as efficiently as possible.

14.1. WHAT INFLUENCES VIRTUAL MACHINE PERFORMANCE

VMs are run as user-space processes on the host. The hypervisor therefore needs to convert the host's system resources so that the VMs can use them. As a consequence, a portion of the resources is consumed by the conversion, and the VM therefore cannot achieve the same performance efficiency as the host.

The impact of virtualization on system performance

More specific reasons for VM performance loss include:

- Virtual CPUs (vCPUs) are implemented as threads on the host, handled by the Linux scheduler.
- VMs do not automatically inherit optimization features, such as NUMA or huge pages, from the host kernel.
- Disk and network I/O settings of the host might have a significant performance impact on the VM.
- Network traffic typically travels to a VM through a software-based bridge.
- Depending on the host devices and their models, there might be significant overhead due to emulation of particular hardware.

The severity of the virtualization impact on the VM performance is influenced by a variety of factors, which include:

- The number of concurrently running VMs.
- The amount of virtual devices used by each VM.
- The device types used by the VMs.

Reducing VM performance loss

RHEL 8 provides a number of features you can use to reduce the negative performance effects of virtualization. Notably:

- [The **tuned** service](#) can automatically optimize the resource distribution and performance of your VMs.
- [Block I/O tuning](#) can improve the performances of the VM's block devices, such as disks.
- [NUMA tuning](#) can increase vCPU performance.
- [Virtual networking](#) can be optimized in various ways.

**IMPORTANT**

Tuning VM performance can have adverse effects on other virtualization functions. For example, it can make migrating the modified VM more difficult.

14.2. OPTIMIZING VIRTUAL MACHINE PERFORMANCE USING TUNED

The **tuned** utility is a tuning profile delivery mechanism that adapts RHEL for certain workload characteristics, such as requirements for CPU-intensive tasks or storage-network throughput responsiveness. It provides a number of tuning profiles that are pre-configured to enhance performance and reduce power consumption in a number of specific use cases. You can edit these profiles or create new profiles to create performance solutions tailored to your environment, including virtualized environments.

To optimize RHEL 8 for virtualization, use the following profiles:

- For RHEL 8 virtual machines, use the **virtual-guest** profile. It is based on the generally applicable **throughput-performance** profile, but also decreases the swappiness of virtual memory.
- For RHEL 8 virtualization hosts, use the **virtual-host** profile. This enables more aggressive writeback of dirty memory pages, which benefits the host performance.

Prerequisites

- The **tuned** service is [installed and enabled](#).

Procedure

To enable a specific **tuned** profile:

1. List the available **tuned** profiles.

```
# tuned-adm list
```

Available profiles:

```
- balanced          - General non-specialized tuned profile
- desktop           - Optimize for the desktop use-case
[...]
- virtual-guest     - Optimize for running inside a virtual guest
- virtual-host      - Optimize for running KVM guests
Current active profile: balanced
```

2. **Optional:** Create a new **tuned** profile or edit an existing **tuned** profile.
For more information, see [Customizing tuned profiles](#).
3. Activate a **tuned** profile.

```
# tuned-adm profile selected-profile
```

- To optimize a virtualization host, use the *virtual-host* profile.

```
# tuned-adm profile virtual-host
```

- On a RHEL guest operating system, use the *virtual-guest* profile.

```
# tuned-adm profile virtual-guest
```

Additional resources

- For more information about **tuned** and **tuned** profiles, see [Monitoring and managing system status and performance](#).

14.3. CONFIGURING VIRTUAL MACHINE MEMORY

To improve the performance of a virtual machine (VM), you can assign additional host RAM to the VM. Similarly, you can decrease the amount of memory allocated to a VM so the host memory can be allocated to other VMs or tasks.

To perform these actions, you can use [the web console](#) or [the command-line interface](#).

14.3.1. Adding and removing virtual machine memory using the web console

To improve the performance of a virtual machine (VM) or to free up the host resources it is using, you can use the web console to adjust amount of memory allocated to the VM.

Prerequisites

- The guest OS is running the memory balloon drivers. To verify this is the case:

1. Ensure the VM's configuration includes the **memballoon** device:

```
# virsh dumpxml testguest | grep memballoon
<memballoon model='virtio'>
  </memballoon>
```

If this commands displays any output and the model is not set to **none**, the **memballoon** device is present.

2. Ensure the balloon drivers are running in the guest OS.
 - In Windows guests, the drivers are installed as a part of the **virtio-win** driver package. For instructions, see [Installing paravirtualized KVM drivers for Windows virtual machines](#).
 - In Linux guests, the drivers are generally included by default and activate when the **memballoon** device is present.
- The web console VM plug-in [is installed on your system](#).

Procedure

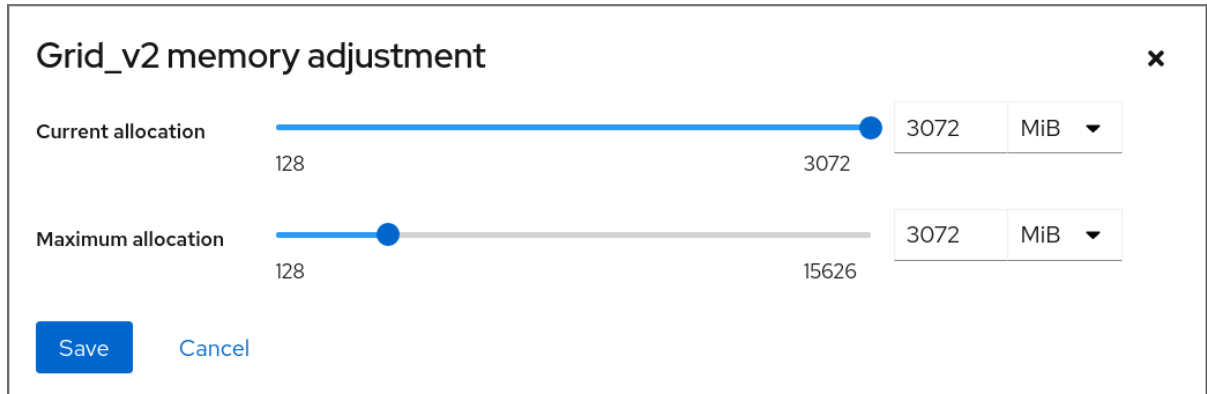

1. **Optional:** Obtain the information about the maximum memory and currently used memory for a VM. This will serve as a baseline for your changes, and also for verification.

```
# virsh dominfo testguest
Max memory: 2097152 KiB
Used memory: 2097152 KiB
```

2. In the **Virtual Machines** interface, click the VM whose information you want to see.

A new page opens with an Overview section with basic information about the selected VM and a Console section to access the VM's graphical interface.

- Click **edit** next to the **Memory** line in the Overview pane.
The **Memory Adjustment** dialog appears.

The dialog box titled "Grid_v2 memory adjustment" contains two sliders and two input fields. The "Current allocation" slider ranges from 128 to 3072, with a blue dot at 3072. The "Maximum allocation" slider ranges from 128 to 15626, with a blue dot at 3072. Both sliders have corresponding input fields on the right showing "3072" and a unit dropdown menu set to "MiB". At the bottom left are "Save" and "Cancel" buttons.

- Configure the virtual CPUs for the selected VM.
 - **Maximum allocation** - Sets the maximum amount of host memory that the VM can use for its processes. You can specify the maximum memory when creating the VM or increase it later. You can specify memory as multiples of MiB or GiB.
Adjusting maximum memory allocation is only possible on a shut-off VM.
 - **Current allocation** - Sets the actual amount of memory allocated to the VM. This value can be less than the Maximum allocation but cannot exceed it. You can adjust the value to regulate the memory available to the VM for its processes. You can specify memory as multiples of MiB or GiB.
If you do not specify this value, the default allocation is the **Maximum allocation** value.
- Click **Save**.
The memory allocation of the VM is adjusted.

Additional resources

- For instructions for adjusting VM memory setting using the command-line interface, see [Section 14.3.2, "Adding and removing virtual machine memory using the command-line interface"](#).
- To optimize how the VM uses the allocated memory, you can modify your vCPU setting. For more information, see [Section 14.5, "Optimizing virtual machine CPU performance"](#).

14.3.2. Adding and removing virtual machine memory using the command-line interface

To improve the performance of a virtual machine (VM) or to free up the host resources it is using, you can use the CLI to adjust amount of memory allocated to the VM.

Prerequisites

- The guest OS is running the memory balloon drivers. To verify this is the case:
 - Ensure the VM's configuration includes the **memballoon** device:

```
# virsh dumpxml testguest | grep memballoon
<memballoon model='virtio'>
  </memballoon>
```

If this commands displays any output and the model is not set to **none**, the **memballoon** device is present.

2. Ensure the balloon drivers are running in the guest OS.
 - In Windows guests, the drivers are installed as a part of the **virtio-win** driver package. For instructions, see [Installing paravirtualized KVM drivers for Windows virtual machines](#).
 - In Linux guests, the drivers are generally included by default and activate when the **memballoon** device is present.

Procedure

1. **Optional:** Obtain the information about the maximum memory and currently used memory for a VM. This will serve as a baseline for your changes, and also for verification.

```
# virsh dominfo testguest
Max memory: 2097152 KiB
Used memory: 2097152 KiB
```

2. Adjust the maximum memory allocated to a VM. Increasing this value improves the performance potential of the VM, and reducing the value lowers the performance footprint the VM has on your host. Note that this change can only be performed on a shut-off VM, so adjusting a running VM requires a reboot to take effect.

For example, to change the maximum memory that the *testguest* VM can use to 4096 MiB:

```
# virt-xml testguest --edit --memory memory=4096,currentMemory=4096
Domain 'testguest' defined successfully.
Changes will take effect after the domain is fully powered off.
```

1. **Optional:** You can also adjust the memory currently used by the VM, up to the maximum allocation. This regulates the memory load that the VM has on the host until the next reboot, without changing the maximum VM allocation.

```
# virsh setmem testguest --current 2048
```

Verification

1. Confirm that the memory used by the VM has been updated:

```
# virsh dominfo testguest
Max memory: 4194304 KiB
Used memory: 2097152 KiB
```

2. **Optional:** If you adjusted the current VM memory, you can obtain the memory balloon statistics of the VM to evaluate how effectively it regulates its memory use.

```
# virsh domstats --balloon testguest
```

```

Domain: 'testquest'
  balloon.current=365624
  balloon.maximum=4194304
  balloon.swap_in=0
  balloon.swap_out=0
  balloon.major_fault=306
  balloon.minor_fault=156117
  balloon.unused=3834448
  balloon.available=4035008
  balloon.usable=3746340
  balloon.last-update=1587971682
  balloon.disk_caches=75444
  balloon.hugetlb_pgalloc=0
  balloon.hugetlb_pgfail=0
  balloon.rss=1005456

```

Additional resources

- For instructions for adjusting VM memory setting using the web console, see [Section 14.3.1, “Adding and removing virtual machine memory using the web console”](#).
- To optimize how the VM uses the allocated memory, you can modify your vCPU setting. For more information, see [Section 14.5, “Optimizing virtual machine CPU performance”](#).

14.3.3. Additional resources

- To increase the maximum memory of a running VM, you can attach a memory device to the VM. This is also referred to as **memory hot plug**. For details, see [Attaching devices to virtual machines](#).
Note that removing a memory device from a VM, also known as **memory hot unplug**, is not supported in RHEL 8, and Red Hat highly discourages its use.

14.4. OPTIMIZING VIRTUAL MACHINE I/O PERFORMANCE

The input and output (I/O) capabilities of a virtual machine (VM) can significantly limit the VM’s overall efficiency. To address this, you can optimize a VM’s I/O by configuring block I/O parameters.

14.4.1. Tuning block I/O in virtual machines

When multiple block devices are being used by one or more VMs, it might be important to adjust the I/O priority of specific virtual devices by modifying their *I/O weights*.

Increasing the I/O weight of a device increases its priority for I/O bandwidth, and therefore provides it with more host resources. Similarly, reducing a device’s weight makes it consume less host resources.

NOTE

Each device’s **weight** value must be within the **100 to 1000** range. Alternatively, the value can be **0**, which removes that device from per-device listings.

Procedure

To display and set a VM’s block I/O parameters:

1. Display the current **<blkio>** parameters for a VM:

```
# virsh dumpxml VM-name
```

```
<domain>
[...]
<blkiotune>
  <weight>800</weight>
  <device>
    <path>/dev/sda</path>
    <weight>1000</weight>
  </device>
  <device>
    <path>/dev/sdb</path>
    <weight>500</weight>
  </device>
</blkiotune>
[...]
</domain>
```

2. Edit the I/O weight of a specified device:

```
# virsh blkiotune VM-name --device-weights device, I/O-weight
```

For example, the following changes the weight of the `/dev/sda` device in the `liftbrul` VM to 500.

```
# virsh blkiotune liftbrul --device-weights /dev/sda, 500
```

14.4.2. Disk I/O throttling in virtual machines

When several VMs are running simultaneously, they can interfere with system performance by using excessive disk I/O. Disk I/O throttling in KVM virtualization provides the ability to set a limit on disk I/O requests sent from the VMs to the host machine. This can prevent a VM from over-utilizing shared resources and impacting the performance of other VMs.

To enable disk I/O throttling, set a limit on disk I/O requests sent from each block device attached to VMs to the host machine.

Procedure

1. Use the **virsh domblklist** command to list the names of all the disk devices on a specified VM.

```
# virsh domblklist rollin-coal
Target    Source
-----
vda       /var/lib/libvirt/images/rollin-coal.qcow2
sda       -
sdb       /home/horridly-demanding-processes.iso
```

2. Find the host block device where the virtual disk that you want to throttle is mounted.
For example, if you want to throttle the **sdb** virtual disk from the previous step, the following output shows that the disk is mounted on the **/dev/nvme0n1p3** partition.

```
$ lsblk
```

```

NAME                                MAJ:MIN RM  SIZE RO TYPE  MOUNTPOINT
zram0                               252:0    0   4G  0 disk  [SWAP]
nvme0n1                             259:0    0 238.5G  0 disk

```

- Set I/O limits for the block device using the **virsh blkiotune** command.

```
# virsh blkiotune VM-name --parameter device,limit
```

The following example throttles the **sdb** disk on the **rollin-coal** VM to 1000 read and write I/O operations per second and to 50 MB per second read and write throughput.

```
# virsh blkiotune rollin-coal --device-read-iops-sec /dev/nvme0n1p3,1000 --device-
write-iops-sec /dev/nvme0n1p3,1000 --device-write-bytes-sec
/dev/nvme0n1p3,52428800 --device-read-bytes-sec /dev/nvme0n1p3,52428800
```

Additional information

- Disk I/O throttling can be useful in various situations, for example when VMs belonging to different customers are running on the same host, or when quality of service guarantees are given for different VMs. Disk I/O throttling can also be used to simulate slower disks.
- I/O throttling can be applied independently to each block device attached to a VM and supports limits on throughput and I/O operations.
- Red Hat does not support using the **virsh blkdeviotune** command to configure I/O throttling in VMs. For more information on unsupported features when using RHEL 8 as a VM host, see [Unsupported features in RHEL 8 virtualization](#).

14.4.3. Enabling multi-queue virtio-scsi

When using **virtio-scsi** storage devices in your virtual machines (VMs), the *multi-queue virtio-scsi* feature provides improved storage performance and scalability. It enables each virtual CPU (vCPU) to have a separate queue and interrupt to use without affecting other vCPUs.

Procedure

- To enable multi-queue virtio-scsi support for a specific VM, add the following to the VM's XML configuration, where *N* is the total number of vCPU queues:

```
<controller type='scsi' index='0' model='virtio-scsi'>
  <driver queues='N' />
</controller>
```

14.5. OPTIMIZING VIRTUAL MACHINE CPU PERFORMANCE

Much like physical CPUs in host machines, vCPUs are critical to virtual machine (VM) performance. As a result, optimizing vCPUs can have a significant impact on the resource efficiency of your VMs. To optimize your vCPU:

1. Adjust how many host CPUs are assigned to the VM. You can do this using [the CLI](#) or [the web console](#).
2. Ensure that the vCPU model is aligned with the CPU model of the host. For example, to set the *testquest1* VM to use the CPU model of the host:

```
# virt-xml testquest1 --edit --cpu host-model
```

3. [Deactivate kernel same-page merging \(KSM\)](#) .
4. If your host machine uses Non-Uniform Memory Access (NUMA), you can also **configure NUMA** for its VMs. This maps the host's CPU and memory processes onto the CPU and memory processes of the VM as closely as possible. In effect, NUMA tuning provides the vCPU with a more streamlined access to the system memory allocated to the VM, which can improve the vCPU processing effectiveness.
For details, see [Section 14.5.3, "Configuring NUMA in a virtual machine"](#) and [Section 14.5.4, "Sample vCPU performance tuning scenario"](#).

14.5.1. Adding and removing virtual CPUs using the command-line interface

To increase or optimize the CPU performance of a virtual machine (VM), you can add or remove virtual CPUs (vCPUs) assigned to the VM.

When performed on a running VM, this is also referred to as vCPU hot plugging and hot unplugging. However, note that vCPU hot unplug is not supported in RHEL 8, and Red Hat highly discourages its use.

Prerequisites

- **Optional:** View the current state of the vCPUs in the targeted VM. For example, to display the number of vCPUs on the *testquest* VM:

```
# virsh vcpucount testquest
maximum    config      4
maximum    live         2
current     config      2
current     live         1
```

This output indicates that *testquest* is currently using 1 vCPU, and 1 more vCPU can be hot plugged to it to increase the VM's performance. However, after reboot, the number of vCPUs *testquest* uses will change to 2, and it will be possible to hot plug 2 more vCPUs.

Procedure

1. Adjust the maximum number of vCPUs that can be attached to a VM, which takes effect on the VM's next boot.

For example, to increase the maximum vCPU count for the *testquest* VM to 8:

```
# virsh setvcpus testquest 8 --maximum --config
```

Note that the maximum may be limited by the CPU topology, host hardware, the hypervisor, and other factors.

2. Adjust the current number of vCPUs attached to a VM, up to the maximum configured in the previous step. For example:

- To increase the number of vCPUs attached to the running *testguest* VM to 4:

```
# virsh setvcpus testguest 4 --live
```

This increases the VM's performance and host load footprint of *testguest* until the VM's next boot.

- To permanently decrease the number of vCPUs attached to the *testguest* VM to 1:

```
# virsh setvcpus testguest 1 --config
```

This decreases the VM's performance and host load footprint of *testguest* after the VM's next boot. However, if needed, additional vCPUs can be hot plugged to the VM to temporarily increase its performance.

Verification

- Confirm that the current state of vCPU for the VM reflects your changes.

```
# virsh vcpucount testguest
maximum    config      8
maximum    live         4
current    config      1
current    live         4
```

Additional resources

- For information on adding and removing vCPUs using the web console, see [Section 14.5.2, "Managing virtual CPUs using the web console"](#).

14.5.2. Managing virtual CPUs using the web console

Using the RHEL 8 web console, you can review and configure virtual CPUs used by virtual machines (VMs) to which the web console is connected.

Prerequisites

- The web console VM plug-in [is installed on your system](#).

Procedure

1. In the **Virtual Machines** interface, click the VM whose information you want to see.
A new page opens with an Overview section with basic information about the selected VM and a Console section to access the VM's graphical interface.
2. Click **edit** next to the number of vCPUs in the Overview pane.
The vCPU details dialog appears.

Grid_v2 vCPU details

vCPU count ⓘ

Sockets ⓘ

vCPU maximum ⓘ

Cores per socket

1 ▼

Threads per core

1 ▼

Apply

Cancel

1. Configure the virtual CPUs for the selected VM.

- **vCPU Count** - The number of vCPUs currently in use.

NOTE

The vCPU count cannot be greater than the vCPU Maximum.

- **vCPU Maximum** - The maximum number of virtual CPUs that can be configured for the VM. If this value is higher than the **vCPU Count**, additional vCPUs can be attached to the VM.
- **Sockets** - The number of sockets to expose to the VM.
- **Cores per socket** - The number of cores for each socket to expose to the VM.
- **Threads per core** - The number of threads for each core to expose to the VM.
Note that the **Sockets**, **Cores per socket** and **Threads per core** options adjust the CPU topology of the VM. This may be beneficial for vCPU performance and may impact the functionality of certain software in the guest OS. If a different setting is not required by your deployment, keep the default values.

2. Click **Apply**.

The virtual CPUs for the VM are configured.

NOTE

Changes to virtual CPU settings only take effect after the VM is restarted.

Additional resources:

- For information on managing your vCPUs using the command-line interface, see [Section 14.5.1, “Adding and removing virtual CPUs using the command-line interface”](#).

14.5.3. Configuring NUMA in a virtual machine

The following methods can be used to configure Non-Uniform Memory Access (NUMA) settings of a virtual machine (VM) on a RHEL 8 host.

Prerequisites

- The host is a NUMA-compatible machine. To detect whether this is the case, use the **virsh nodeinfo** command and see the **NUMA cell(s)** line:

```
# virsh nodeinfo
CPU model:      x86_64
CPU(s):         48
CPU frequency:  1200 MHz
CPU socket(s):  1
Core(s) per socket: 12
Thread(s) per core: 2
NUMA cell(s):   2
Memory size:    67012964 KiB
```

If the value of the line is 2 or greater, the host is NUMA-compatible.

Procedure

For ease of use, you can set up a VM's NUMA configuration using automated utilities and services. However, manual NUMA setup is more likely to yield a significant performance improvement.

Automatic methods

- Set the VM's NUMA policy to **Preferred**. For example, to do so for the *testguest5* VM:

```
# virt-xml testguest5 --edit --vcpus placement=auto
# virt-xml testguest5 --edit --numatune mode=preferred
```

- Enable automatic NUMA balancing on the host:

```
# echo 1 > /proc/sys/kernel/numa_balancing
```

- Use the **numad** command to automatically align the VM CPU with memory resources.

```
# numad
```

Manual methods

1. Pin specific vCPU threads to a specific host CPU or range of CPUs. This is also possible on non-NUMA hosts and VMs, and is recommended as a safe method of vCPU performance improvement.

For example, the following commands pin vCPU threads 0 to 5 of the *testguest6* VM to host CPUs 1, 3, 5, 7, 9, and 11, respectively:

```
# virsh vcpupin testguest6 0 1
# virsh vcpupin testguest6 1 3
# virsh vcpupin testguest6 2 5
# virsh vcpupin testguest6 3 7
# virsh vcpupin testguest6 4 9
# virsh vcpupin testguest6 5 11
```

Afterwards, you can verify whether this was successful:

```
# virsh vcpupin testguest6
VCPU  CPU Affinity
-----
```

```

0   1
1   3
2   5
3   7
4   9
5  11

```

- After pinning vCPU threads, you can also pin QEMU process threads associated with a specified VM to a specific host CPU or range of CPUs. For example, the following commands pin the QEMU process thread of *testquest6* to CPUs 13 and 15, and verify this was successful:

```

# virsh emulatorpin testquest6 13,15
# virsh emulatorpin testquest6
emulator: CPU Affinity
-----
*: 13,15

```

- Finally, you can also specify which host NUMA nodes will be assigned specifically to a certain VM. This can improve the host memory usage by the VM's vCPU. For example, the following commands set *testquest6* to use host NUMA nodes 3 to 5, and verify this was successful:

```

# virsh numatune testquest6 --nodeset 3-5
# virsh numatune testquest6

```

Additional resources

- Note that for best performance results, it is recommended to use all of the manual tuning methods listed above. For an example of such a configuration, see [Section 14.5.4, “Sample vCPU performance tuning scenario”](#).
- To see the current NUMA configuration of your system, you can use the **numastat** utility. For details on using **numastat**, see [Section 14.7, “Virtual machine performance monitoring tools”](#).
- NUMA tuning is currently not possible to perform on IBM Z hosts. For further information, see [How virtualization on IBM Z differs from AMD64 and Intel 64](#).

14.5.4. Sample vCPU performance tuning scenario

To obtain the best vCPU performance possible, Red Hat recommends using manual **vcupin**, **emulatorpin**, and **numatune** settings together, for example like in the following scenario.

Starting scenario

- Your host has the following hardware specifics:
 - 2 NUMA nodes
 - 3 CPU cores on each node
 - 2 threads on each core

The output of **virsh nodeinfo** of such a machine would look similar to:

```

# virsh nodeinfo

```

```

CPU model:      x86_64
CPU(s):         12
CPU frequency:  3661 MHz
CPU socket(s):  2
Core(s) per socket: 3
Thread(s) per core: 2
NUMA cell(s):   2
Memory size:    31248692 KiB

```

- You intend to modify an existing VM to have 8 vCPUs, which means that it will not fit in a single NUMA node.

Therefore, you should distribute 4 vCPUs on each NUMA node and make the vCPU topology resemble the host topology as closely as possible. This means that vCPUs that run as sibling threads of a given physical CPU should be pinned to host threads on the same core. For details, see the *Solution* below:

Solution

1. Obtain the information on the host topology:

```
# virsh capabilities
```

The output should include a section that looks similar to the following:

```

<topology>
  <cells num="2">
    <cell id="0">
      <memory unit="KiB">15624346</memory>
      <pages unit="KiB" size="4">3906086</pages>
      <pages unit="KiB" size="2048">0</pages>
      <pages unit="KiB" size="1048576">0</pages>
      <distances>
        <sibling id="0" value="10" />
        <sibling id="1" value="21" />
      </distances>
      <cpus num="6">
        <cpu id="0" socket_id="0" core_id="0" siblings="0,3" />
        <cpu id="1" socket_id="0" core_id="1" siblings="1,4" />
        <cpu id="2" socket_id="0" core_id="2" siblings="2,5" />
        <cpu id="3" socket_id="0" core_id="0" siblings="0,3" />
        <cpu id="4" socket_id="0" core_id="1" siblings="1,4" />
        <cpu id="5" socket_id="0" core_id="2" siblings="2,5" />
      </cpus>
    </cell>
    <cell id="1">
      <memory unit="KiB">15624346</memory>
      <pages unit="KiB" size="4">3906086</pages>
      <pages unit="KiB" size="2048">0</pages>
      <pages unit="KiB" size="1048576">0</pages>
      <distances>
        <sibling id="0" value="21" />
        <sibling id="1" value="10" />
      </distances>
      <cpus num="6">
        <cpu id="6" socket_id="1" core_id="3" siblings="6,9" />

```

```

<cpu id="7" socket_id="1" core_id="4" siblings="7,10" />
<cpu id="8" socket_id="1" core_id="5" siblings="8,11" />
<cpu id="9" socket_id="1" core_id="3" siblings="6,9" />
<cpu id="10" socket_id="1" core_id="4" siblings="7,10" />
<cpu id="11" socket_id="1" core_id="5" siblings="8,11" />
</cpus>
</cell>
</cells>
</topology>

```

2. **Optional:** Test the performance of the VM using [the applicable tools and utilities](#).
3. Set up and mount 1 GiB huge pages on the host:

- a. Add the following line to the host's kernel command line:

```
default_hugepagesz=1G hugepagesz=1G
```

- b. Create the **/etc/systemd/system/hugetlb-gigantic-pages.service** file with the following content:

```

[Unit]
Description=HugeTLB Gigantic Pages Reservation
DefaultDependencies=no
Before=dev-hugepages.mount
ConditionPathExists=/sys/devices/system/node
ConditionKernelCommandLine=hugepagesz=1G

[Service]
Type=oneshot
RemainAfterExit=yes
ExecStart=/etc/systemd/hugetlb-reserve-pages.sh

[Install]
WantedBy=sysinit.target

```

- c. Create the **/etc/systemd/hugetlb-reserve-pages.sh** file with the following content:

```

#!/bin/sh

nodes_path=/sys/devices/system/node/
if [ ! -d $nodes_path ]; then
    echo "ERROR: $nodes_path does not exist"
    exit 1
fi

reserve_pages()
{
    echo $1 > $nodes_path/$2/hugepages/hugepages-1048576kB/nr_hugepages
}

reserve_pages 4 node1
reserve_pages 4 node2

```

This reserves four 1GiB huge pages from *node1* and four 1GiB huge pages from *node2*.

- d. Make the script created in the previous step executable:

```
# chmod +x /etc/systemd/hugetlb-reserve-pages.sh
```

- e. Enable huge page reservation on boot:

```
# systemctl enable hugetlb-gigantic-pages
```

4. Use the **virsh edit** command to edit the XML configuration of the VM you wish to optimize, in this example *super-VM*:

```
# virsh edit super-vm
```

5. Adjust the XML configuration of the VM in the following way:

- a. Set the VM to use 8 static vCPUs. Use the **<vcpu/>** element to do this.
- b. Pin each of the vCPU threads to the corresponding host CPU threads that it mirrors in the topology. To do so, use the **<vcpupin/>** elements in the **<cputune>** section.
Note that, as shown by the **virsh capabilities** utility above, host CPU threads are not ordered sequentially in their respective cores. In addition, the vCPU threads should be pinned to the highest available set of host cores on the same NUMA node. For a table illustration, see the **Additional Resources** section below.

The XML configuration for steps a. and b. can look similar to:

```
<cputune>
  <vcpupin vcpu='0' cpuset='1' />
  <vcpupin vcpu='1' cpuset='4' />
  <vcpupin vcpu='2' cpuset='2' />
  <vcpupin vcpu='3' cpuset='5' />
  <vcpupin vcpu='4' cpuset='7' />
  <vcpupin vcpu='5' cpuset='10' />
  <vcpupin vcpu='6' cpuset='8' />
  <vcpupin vcpu='7' cpuset='11' />
  <emulatorpin cpuset='6,9' />
</cputune>
```

- c. Set the VM to use 1 GiB huge pages:

```
<memoryBacking>
  <hugepages>
    <page size='1' unit='GiB' />
  </hugepages>
</memoryBacking>
```

- d. Configure the VM's NUMA nodes to use memory from the corresponding NUMA nodes on the host. To do so, use the **<memnode/>** elements in the **<numatune/>** section:

```
<numatune>
  <memory mode="preferred" nodeset="1" />
  <memnode cellid="0" mode="strict" nodeset="0" />
  <memnode cellid="1" mode="strict" nodeset="1" />
</numatune>
```

- e. Ensure the CPU mode is set to **host-passthrough**, and that the CPU uses cache in **passthrough** mode:

```
<cpu mode="host-passthrough">
  <topology sockets="2" cores="2" threads="2"/>
  <cache mode="passthrough"/>
```

Verification

1. Confirm that the resulting XML configuration of the VM includes a section similar to the following:

```
[...]
<memoryBacking>
  <hugepages>
    <page size='1' unit='GiB'/>
  </hugepages>
</memoryBacking>
<vcpu placement='static'>8</vcpu>
<cputune>
  <vcpupin vcpu='0' cpuset='1'/>
  <vcpupin vcpu='1' cpuset='4'/>
  <vcpupin vcpu='2' cpuset='2'/>
  <vcpupin vcpu='3' cpuset='5'/>
  <vcpupin vcpu='4' cpuset='7'/>
  <vcpupin vcpu='5' cpuset='10'/>
  <vcpupin vcpu='6' cpuset='8'/>
  <vcpupin vcpu='7' cpuset='11'/>
  <emulatorpin cpuset='6,9'/>
</cputune>
<numatune>
  <memory mode="preferred" nodeset="1"/>
  <memnode cellid="0" mode="strict" nodeset="0"/>
  <memnode cellid="1" mode="strict" nodeset="1"/>
</numatune>
<cpu mode="host-passthrough">
  <topology sockets="2" cores="2" threads="2"/>
  <cache mode="passthrough"/>
  <numa>
    <cell id="0" cpus="0-3" memory="2" unit="GiB">
      <distances>
        <sibling id="0" value="10"/>
        <sibling id="1" value="21"/>
      </distances>
    </cell>
    <cell id="1" cpus="4-7" memory="2" unit="GiB">
      <distances>
        <sibling id="0" value="21"/>
        <sibling id="1" value="10"/>
      </distances>
    </cell>
  </numa>
</cpu>
</domain>
```

2. **Optional:** Test the performance of the VM using [the applicable tools and utilities](#) to evaluate the impact of the VM's optimization.

Additional resources

- The following tables illustrate the connections between the vCPUs and the host CPUs they should be pinned to:

Table 14.1. Host topology

CPU threads	0	3	1	4	2	5	6	9	7	10	8	11
Cores	0		1		2		3		4		5	
Sockets	0						1					
NUMA nodes	0						1					

Table 14.2. VM topology

vCPU threads	0	1	2	3	4	5	6	7
Cores	0		1		2		3	
Sockets	0				1			
NUMA nodes	0				1			

Table 14.3. Combined host and VM topology

vCPU threads			0	1	2	3			4	5	6	7
Host CPU threads	0	3	1	4	2	5	6	9	7	10	8	11
Cores	0		1		2		3		4		5	
Sockets	0						1					
NUMA nodes	0						1					

In this scenario, there are 2 NUMA nodes and 8 vCPUs. Therefore, 4 vCPU threads should be pinned to each node.

In addition, Red Hat recommends leaving at least a single CPU thread available on each node for host system operations.

Because in this example, each NUMA node houses 3 cores, each with 2 host CPU threads, the set for node 0 translates as follows:

```
<vcpupin vcpu='0' cpuset='1'/>
<vcpupin vcpu='1' cpuset='4'/>
<vcpupin vcpu='2' cpuset='2'/>
<vcpupin vcpu='3' cpuset='5'/>
```

14.5.5. Deactivating kernel same-page merging

Although kernel same-page merging (KSM) improves memory density, it increases CPU utilization, and might adversely affect overall performance depending on the workload. In such cases, you can improve the virtual machine (VM) performance by deactivating KSM.

Depending on your requirements, you can either deactivate KSM for a single session or persistently.

Procedure

- To deactivate KSM for a single session, use the **systemctl** utility to stop **ksm** and **ksmtuned** services.

```
# systemctl stop ksm
# systemctl stop ksmtuned
```

- To deactivate KSM persistently, use the **systemctl** utility to disable **ksm** and **ksmtuned** services.

```
# systemctl disable ksm
Removed /etc/systemd/system/multi-user.target.wants/ksm.service.
# systemctl disable ksmtuned
Removed /etc/systemd/system/multi-user.target.wants/ksmtuned.service.
```

NOTE

Memory pages shared between VMs before deactivating KSM will remain shared. To stop sharing, delete all the **PageKSM** pages in the system using the following command:

```
# echo 2 > /sys/kernel/mm/ksm/run
```

After anonymous pages replace the KSM pages, the **khugepaged** kernel service will rebuild transparent hugepages on the VM's physical memory.

14.6. OPTIMIZING VIRTUAL MACHINE NETWORK PERFORMANCE

Due to the virtual nature of a VM's network interface card (NIC), the VM loses a portion of its allocated host network bandwidth, which can reduce the overall workload efficiency of the VM. The following tips can minimize the negative impact of virtualization on the virtual NIC (vNIC) throughput.

Procedure

Use any of the following methods and observe if it has a beneficial effect on your VM network performance:

Enable the **vhost_net** module

On the host, ensure the **vhost_net** kernel feature is enabled:

```
# lsmod | grep vhost
vhost_net      32768  1
vhost          53248  1 vhost_net
tap            24576  1 vhost_net
tun            57344  6 vhost_net
```

If the output of this command is blank, enable the **vhost_net** kernel module:

```
# modprobe vhost_net
```

Set up multi-queue virtio-net

To set up the *multi-queue virtio-net* feature for a VM, use the **virsh edit** command to edit to the XML configuration of the VM. In the XML, add the following to the **<devices>** section, and replace **N** with the number of vCPUs in the VM, up to 16:

```
<interface type='network'>
  <source network='default'/>
  <model type='virtio'/>
  <driver name='vhost' queues='N'/>
</interface>
```

If the VM is running, restart it for the changes to take effect.

Batching network packets

In Linux VM configurations with a long transmission path, batching packets before submitting them to the kernel may improve cache utilization. To set up packet batching, use the following command on the host, and replace *tap0* with the name of the network interface that the VMs use:

```
# ethtool -C tap0 rx-frames 128
```

SR-IOV

If your host NIC supports SR-IOV, use SR-IOV device assignment for your vNICs. For more information, see [Managing SR-IOV devices](#).

Additional resources

- For additional information on virtual network connection types and tips for usage, see [Understanding virtual networking](#).

14.7. VIRTUAL MACHINE PERFORMANCE MONITORING TOOLS

To identify what consumes the most VM resources and which aspect of VM performance needs optimization, performance diagnostic tools, both general and VM-specific, can be used.

Default OS performance monitoring tools

For standard performance evaluation, you can use the utilities provided by default by your host and guest operating systems:

- On your RHEL 8 host, as root, use the **top** utility or the **system monitor** application, and look for **qemu** and **virt** in the output. This shows how much host system resources your VMs are consuming.

- If the monitoring tool displays that any of the **qemu** or **virt** processes consume a large portion of the host CPU or memory capacity, use the **perf** utility to investigate. For details, see below.
- In addition, if a **vhost_net** thread process, named for example `vhost_net-1234`, is displayed as consuming an excessive amount of host CPU capacity, consider using [virtual network optimization features](#), such as **multi-queue virtio-net**.
- On the guest operating system, use performance utilities and applications available on the system to evaluate which processes consume the most system resources.
 - On Linux systems, you can use the **top** utility.
 - On Windows systems, you can use the **Task Manager** application.

perf kvm

You can use the **perf** utility to collect and analyze virtualization-specific statistics about the performance of your RHEL 8 host. To do so:

1. On the host, install the *perf* package:

```
# yum install perf
```

2. Use one of the **perf kvm stat** commands to display perf statistics for your virtualization host:
 - For real-time monitoring of your hypervisor, use the **perf kvm stat live** command.
 - To log the perf data of your hypervisor over a period of time, activate the logging using the **perf kvm stat record** command. After the command is canceled or interrupted, the data is saved in the **perf.data.guest** file, which can be analyzed using the **perf kvm stat report** command.
3. Analyze the **perf** output for types of **VM-EXIT** events and their distribution. For example, the **PAUSE_INSTRUCTION** events should be infrequent, but in the following output, the high occurrence of this event suggests that the host CPUs are not handling the running vCPUs well. In such a scenario, consider shutting down some of your active VMs, removing vCPUs from these VMs, or [tuning the performance of the vCPUs](#).

```
# perf kvm stat report
```

Analyze events for all VMs, all VCPUs:

VM-EXIT	Samples	Samples%	Time%	Min Time	Max Time	Avg time
EXTERNAL_INTERRUPT	365634	31.59%	18.04%	0.42us	58780.59us	204.08us (+- 0.99%)
MSR_WRITE	293428	25.35%	0.13%	0.59us	17873.02us	1.80us (+- 4.63%)
PREEMPTION_TIMER	276162	23.86%	0.23%	0.51us	21396.03us	3.38us (+- 5.19%)
PAUSE_INSTRUCTION	189375	16.36%	11.75%	0.72us	29655.25us	256.77us (+- 0.70%)
HLT	20440	1.77%	69.83%	0.62us	79319.41us	14134.56us (+- 0.79%)
VMCALL	12426	1.07%	0.03%	1.02us	5416.25us	8.77us (+- 7.36%)

```
)
  EXCEPTION_NMI      27  0.00%  0.00%  0.69us  1.34us  0.98us ( +-
3.50% )
  EPT_MISCONFIG      5  0.00%  0.00%  5.15us  10.85us  7.88us ( +-
11.67% )
```

Total Samples:1157497, Total events handled time:413728274.66us.

Other event types that can signal problems in the output of **perf kvm stat** include:

- **INSN_EMULATION** - suggests suboptimal [VM I/O configuration](#).

For more information on using **perf** to monitor virtualization performance, see the **perf-kvm** man page.

numastat

To see the current NUMA configuration of your system, you can use the **numastat** utility, which is provided by installing the **numactl** package.

The following shows a host with 4 running VMs, each obtaining memory from multiple NUMA nodes. This is not optimal for vCPU performance, and [warrants adjusting](#):

numastat -c qemu-kvm

Per-node process memory usage (in MBs)

PID	Node 0	Node 1	Node 2	Node 3	Node 4	Node 5	Node 6	Node 7	Total
51722 (qemu-kvm)	68	16	357	6936	2	3	147	598	8128
51747 (qemu-kvm)	245	11	5	18	5172	2532	1	92	8076
53736 (qemu-kvm)	62	432	1661	506	4851	136	22	445	8116
53773 (qemu-kvm)	1393	3	1	2	12	0	0	6702	8114
Total	1769	463	2024	7462	10037	2672	169	7837	32434

In contrast, the following shows memory being provided to each VM by a single node, which is significantly more efficient.

numastat -c qemu-kvm

Per-node process memory usage (in MBs)

PID	Node 0	Node 1	Node 2	Node 3	Node 4	Node 5	Node 6	Node 7	Total
51747 (qemu-kvm)	0	0	7	0	8072	0	1	0	8080
53736 (qemu-kvm)	0	0	7	0	0	0	8113	0	8120
53773 (qemu-kvm)	0	0	7	0	0	0	1	8110	8118
59065 (qemu-kvm)	0	0	8050	0	0	0	0	0	8051
Total	0	0	8072	0	8072	0	8114	8110	32368

14.8. RELATED INFORMATION

- When using Windows as the guest operating system of your VM, Red Hat recommends applying additional optimization measures. For details, see [Optimizing Windows virtual machines](#).

CHAPTER 15. IMPORTANCE OF POWER MANAGEMENT

Reducing the overall power consumption of computer systems helps to save cost. Effectively optimizing energy consumption of each system component includes studying different tasks that your system performs, and configuring each component to ensure that its performance is correct for that job. Lowering the power consumption of a specific component or of the system as a whole leads to lower heat and performance.

Proper power management results in:

- heat reduction for servers and computing centers
- reduced secondary costs, including cooling, space, cables, generators, and uninterruptible power supplies (UPS)
- extended battery life for laptops
- lower carbon dioxide output
- meeting government regulations or legal requirements regarding Green IT, for example, Energy Star
- meeting company guidelines for new systems

This section describes the information regarding power management of your Red Hat Enterprise Linux systems.

15.1. POWER MANAGEMENT BASICS

Effective power management is built on the following principles:

An idle CPU should only wake up when needed

Since Red Hat Enterprise Linux 6, the kernel runs **tickless**, which means the previous periodic timer interrupts have been replaced with on-demand interrupts. Therefore, idle CPUs are allowed to remain idle until a new task is queued for processing, and CPUs that have entered lower power states can remain in these states longer. However, benefits from this feature can be offset if your system has applications that create unnecessary timer events. Polling events, such as checks for volume changes or mouse movement, are examples of such events.

Red Hat Enterprise Linux includes tools using which you can identify and audit applications on the basis of their CPU usage. For more information see, [Audit and analysis overview](#) and [Tools for auditing](#).

Unused hardware and devices should be disabled completely

This is true for devices that have moving parts, for example, hard disks. In addition to this, some applications may leave an unused but enabled device "open"; when this occurs, the kernel assumes that the device is in use, which can prevent the device from going into a power saving state.

Low activity should translate to low wattage

In many cases, however, this depends on modern hardware and correct BIOS configuration or UEFI on modern systems, including non-x86 architectures. Make sure that you are using the latest official firmware for your systems and that in the power management or device configuration sections of the BIOS the power management features are enabled. Some features to look for include:

- Collaborative Processor Performance Controls (CPPC) support for ARM64

- PowerNV support for IBM Power Systems
- SpeedStep
- PowerNow!
- Cool'n'Quiet
- ACPI (C-state)
- Smart

If your hardware has support for these features and they are enabled in the BIOS, Red Hat Enterprise Linux uses them by default.

Different forms of CPU states and their effects

Modern CPUs together with Advanced Configuration and Power Interface (ACPI) provide different power states. The three different states are:

- Sleep (C-states)
- Frequency and voltage (P-states)
- Heat output (T-states or thermal states)

A CPU running on the lowest sleep state, consumes the least amount of watts, but it also takes considerably more time to wake it up from that state when needed. In very rare cases this can lead to the CPU having to wake up immediately every time it just went to sleep. This situation results in an effectively permanently busy CPU and loses some of the potential power saving if another state had been used.

A turned off machine uses the least amount of power

One of the best ways to save power is to turn off systems. For example, your company can develop a corporate culture focused on "green IT" awareness with a guideline to turn off machines during lunch break or when going home. You also might consolidate several physical servers into one bigger server and virtualize them using the virtualization technology, which is shipped with Red Hat Enterprise Linux.

15.2. AUDIT AND ANALYSIS OVERVIEW

The detailed manual audit, analysis, and tuning of a single system is usually the exception because the time and cost spent to do so typically outweighs the benefits gained from these last pieces of system tuning.

However, performing these tasks once for a large number of nearly identical systems where you can reuse the same settings for all systems can be very useful. For example, consider the deployment of thousands of desktop systems, or an HPC cluster where the machines are nearly identical. Another reason to do auditing and analysis is to provide a basis for comparison against which you can identify regressions or changes in system behavior in the future. The results of this analysis can be very helpful in cases where hardware, BIOS, or software updates happen regularly and you want to avoid any surprises with regard to power consumption. Generally, a thorough audit and analysis gives you a much better idea of what is really happening on a particular system.

Auditing and analyzing a system with regard to power consumption is relatively hard, even with the most modern systems available. Most systems do not provide the necessary means to measure power use via software. Exceptions exist though:

- iLO management console of Hewlett Packard server systems has a power management module that you can access through the web.
- IBM provides a similar solution in their BladeCenter power management module.
- On some Dell systems, the IT Assistant offers power monitoring capabilities as well.

Other vendors are likely to offer similar capabilities for their server platforms, but as can be seen there is no single solution available that is supported by all vendors. Direct measurements of power consumption are often only necessary to maximize savings as far as possible.

15.3. TOOLS FOR AUDITING

Red Hat Enterprise Linux 8 offers tools using which you can perform system auditing and analysis. Most of them can be used as supplementary sources of information in case you want to verify what you have discovered already or in case you need more in-depth information on certain parts.

Many of these tools are used for performance tuning as well, which include:

PowerTOP

It identifies specific components of kernel and user-space applications that frequently wake up the CPU. Use the **powertop** command as root to start the **PowerTop** tool and **powertop --calibrate** to calibrate the power estimation engine. For more information on PowerTop, see [Managing power consumption with PowerTOP](#).

Diskdevstat and netdevstat

They are SystemTap tools that collect detailed information about the disk activity and network activity of all applications running on a system. Using the collected statistics by these tools, you can identify applications that waste power with many small I/O operations rather than fewer, larger operations. Using the **yum install tuned-utils-systemtap kernel-debuginfo** command as root, install the **diskdevstat** and **netdevstat** tool.

To view the detailed information about the disk and network activity, use:

```
# diskdevstat
```

```
PID UID DEV WRITE_CNT WRITE_MIN WRITE_MAX WRITE_AVG READ_CNT
READ_MIN READ_MAX READ_AVG COMMAND
3575 1000 dm-2 59 0.000 0.365 0.006 5 0.000 0.000 0.000
mozStorage #5
3575 1000 dm-2 7 0.000 0.000 0.000 0 0.000 0.000 0.000
localStorage DB
[...]
```

```
# netdevstat
```

```
PID UID DEV XMIT_CNT XMIT_MIN XMIT_MAX XMIT_AVG RECV_CNT
RECV_MIN RECV_MAX RECV_AVG COMMAND
3572 991 enp0s31f6 40 0.000 0.882 0.108 0 0.000 0.000 0.000
openvpn
3575 1000 enp0s31f6 27 0.000 1.363 0.160 0 0.000 0.000 0.000
Socket Thread
[...]
```

With these commands, you can specify three parameters: **update_interval**, **total_duration**, and **display_histogram**.

TuneD

It is a profile-based system tuning tool that uses the **udev** device manager to monitor connected devices, and enables both static and dynamic tuning of system settings. You can use the **tuned-adm recommend** command to determine which profile Red Hat recommends as the most suitable for a particular product. For more information on TuneD, see [Getting started with TuneD](#) and [Customizing TuneD profiles](#). Using the **powertop2tuned** utility, you can create custom TuneD profiles from **PowerTOP** suggestions. For information on the **powertop2tuned** utility, see [Optimizing power consumption](#).

Virtual memory statistics (vmstat)

It is provided by the **procps-ng** package. Using this tool, you can view the detailed information about processes, memory, paging, block I/O, traps, and CPU activity.

To view this information, use:

```
$ vmstat
procs -----memory----- ---swap-- -----io----- -system-- -----cpu-----
 r b swpd free  buff cache  si so bi bo  in cs us sy id wa st
 1 0 0 5805576 380856 4852848 0 0 119 73 814 640 2 2 96 0 0
```

Using the **vmstat -a** command, you can display active and inactive memory. For more information on other **vmstat** options, see the **vmstat** man page.

iostat

It is provided by the **sysstat** package. This tool is similar to **vmstat**, but only for monitoring I/O on block devices. It also provides more verbose output and statistics.

To monitor the system I/O, use:

```
$ iostat
avg-cpu: %user  %nice %system %iowait  %steal   %idle
          2.05   0.46   1.55   0.26   0.00  95.67

Device  tps    kB_read/s    kB_wrtn/s    kB_read    kB_wrtn
nvme0n1 53.54     899.48     616.99    3445229    2363196
dm-0    42.84     753.72     238.71    2886921     914296
dm-1     0.03       0.60       0.00      2292         0
dm-2    24.15     143.12     379.80    548193    1454712
```

blktrace

It provides detailed information about how time is spent in the I/O subsystem.

To view this information in human readable format, use:

```
# blktrace -d /dev/dm-0 -o - | blkparse -i -

253,0 1 1 0.000000000 17694 Q W 76423384 + 8 [kworker/u16:1]
253,0 2 1 0.001926913 0 C W 76423384 + 8 [0]
[...]
```

Here, The first column, **253,0** is the device major and minor tuple. The second column, **1**, gives information about the CPU, followed by columns for timestamps and PID of the process issuing the IO process.

The sixth column, **Q**, shows the event type, the 7th column, **W** for write operation, the 8th column, **76423384**, is the block number, and the **+ 8** is the number of requested blocks.

The last field, **[kworker/u16:1]**, is the process name.

By default, the **blktrace** command runs forever until the process is explicitly killed. Use the **-w** option to specify the run-time duration.

turbostat

It is provided by the **kernel-tools** package. It reports on processor topology, frequency, idle power-state statistics, temperature, and power usage on x86-64 processors.

To view this summary, use:

```
# turbostat

CUID(0): GenuineIntel 0x16 CUID levels; 0x80000008 xlevels; family:model:stepping 0x6:8e:a
(6:142:10)
CUID(1): SSE3 MONITOR SMX EIST TM2 TSC MSR ACPI-TM HT TM
CUID(6): APERF, TURBO, DTS, PTM, HWP, HWPnotify, HWPwindow, HWPcapp, No-HWPpkg,
EPB
[...]
```

By default, **turbostat** prints a summary of counter results for the entire screen, followed by counter results every 5 seconds. Specify a different period between counter results with the **-i** option, for example, execute **turbostat -i 10** to print results every 10 seconds instead.

Turbostat is also useful for identifying servers that are inefficient in terms of power usage or idle time. It also helps to identify the rate of system management interrupts (SMIs) occurring on the system. It can also be used to verify the effects of power management tuning.

cpupower

It is a collection of tools to examine and tune power saving related features of processors. Use the **cpupower** command with the **frequency-info**, **frequency-set**, **idle-info**, **idle-set**, **set**, **info**, and **monitor** options to display and set processor related values.

For example, to view available cpufreq governors, use:

```
$ cpupower frequency-info --governors
analyzing CPU 0:
available cpufreq governors: performance powersave
```

For more information about **cpupower**, see Viewing CPU related information.

GNOME Power Manager

It is a daemon that is installed as part of the GNOME desktop environment. GNOME Power Manager notifies you of changes in your system's power status; for example, a change from battery to AC power. It also reports battery status, and warns you when battery power is low.

Additional resources

- **powertop(1)**, **diskdevstat(8)**, **netdevstat(8)**, **tuned(8)**, **vmstat(8)**, **iostat(1)**, **blktrace(8)**, **blkparse(8)**, and **turbostat(8)** man pages

- **cpupower(1)**, **cpupower-set(1)**, **cpupower-info(1)**, **cpupower-idle(1)**, **cpupower-frequency-set(1)**, **cpupower-frequency-info(1)**, and **cpupower-monitor(1)** man pages

CHAPTER 16. MANAGING POWER CONSUMPTION WITH POWERTOP

As a system administrator, you can use the **PowerTOP** tool to analyze and manage power consumption.

16.1. THE PURPOSE OF POWERTOP

PowerTOP is a program that diagnoses issues related to power consumption and provides suggestions on how to extend battery lifetime.

The **PowerTOP** tool can provide an estimate of the total power usage of the system and also individual power usage for each process, device, kernel worker, timer, and interrupt handler. The tool can also identify specific components of kernel and user-space applications that frequently wake up the CPU.

Red Hat Enterprise Linux 8 uses version 2.x of **PowerTOP**.

16.2. USING POWERTOP

Prerequisites

- To be able to use **PowerTOP**, make sure that the **powertop** package has been installed on your system:

```
# yum install powertop
```

16.2.1. Starting PowerTOP

Procedure

- To run **PowerTOP**, use the following command:

```
# powertop
```

IMPORTANT

Laptops should run on battery power when running the **powertop** command.

16.2.2. Calibrating PowerTOP

Procedure

1. On a laptop, you can calibrate the power estimation engine by running the following command:

```
# powertop --calibrate
```

2. Let the calibration finish without interacting with the machine during the process. Calibration takes time because the process performs various tests, cycles through brightness levels and switches devices on and off.

3. When the calibration process is completed, **PowerTOP** starts as normal. Let it run for approximately an hour to collect data.
When enough data is collected, power estimation figures will be displayed in the first column of the output table.

**NOTE**

Note that **powertop --calibrate** can only be used on laptops.

16.2.3. Setting the measuring interval

By default, **PowerTOP** takes measurements in 20 seconds intervals.

If you want to change this measuring frequency, use the following procedure:

Procedure

- Run the **powertop** command with the **--time** option:

```
# powertop --time=time in seconds
```

16.2.4. Related information

For more details on how to use **PowerTOP**, see the **powertop** man page.

16.3. POWERTOP STATISTICS

While it runs, **PowerTOP** gathers statistics from the system.

PowerTOP's output provides multiple tabs:

- **Overview**
- **Idle stats**
- **Frequency stats**
- **Device stats**
- **Tunables**

You can use the **Tab** and **Shift+Tab** keys to cycle through these tabs.

16.3.1. The Overview tab

In the **Overview** tab, you can view a list of the components that either send wakeups to the CPU most frequently or consume the most power. The items within the **Overview** tab, including processes, interrupts, devices, and other resources, are sorted according to their utilization.

The adjacent columns within the **Overview** tab provide the following pieces of information:

Usage

Power estimation of how the resource is being used.

Events/s

Wakeup per second. The number of wakeups per second indicates how efficiently the services or the devices and drivers of the kernel are performing. Less wakeups means that less power is consumed. Components are ordered by how much further their power usage can be optimized.

Category

Classification of the component; such as process, device, or timer.

Description

Description of the component.

If properly calibrated, a power consumption estimation for every listed item in the first column is shown as well.

Apart from this, the **Overview** tab includes the line with summary statistics such as:

- Total power consumption
- Remaining battery life (only if applicable)
- Summary of total wakeups per second, GPU operations per second, and virtual file system operations per second

16.3.2. The Idle stats tab

The **Idle stats** tab shows usage of C-states for all processors and cores, while the **Frequency stats** tab shows usage of P-states including the Turbo mode, if applicable, for all processors and cores. The duration of C- or P-states is an indication of how well the CPU usage has been optimized. The longer the CPU stays in the higher C- or P-states (for example C4 is higher than C3), the better the CPU usage optimization is. Ideally, residency is 90% or more in the highest C- or P-state when the system is idle.

16.3.3. The Device stats tab

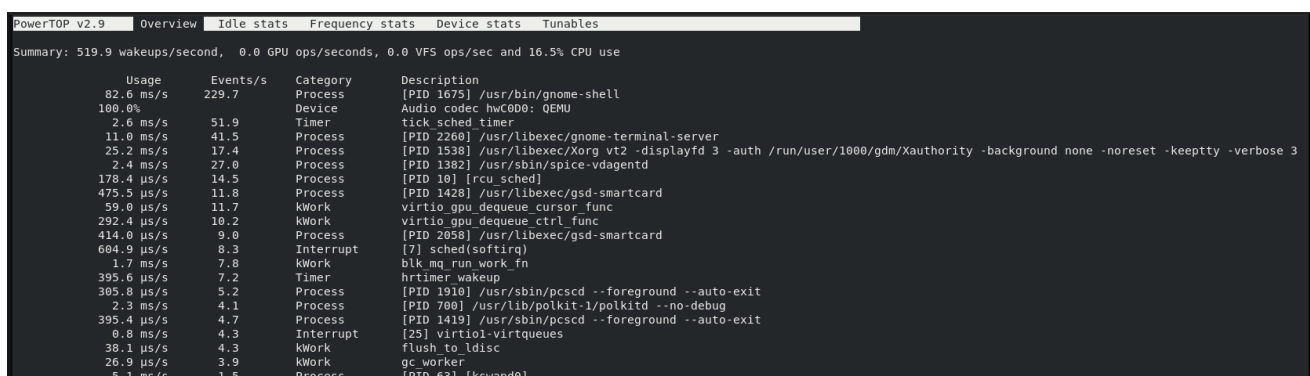

The **Device stats** tab provides similar information to the **Overview** tab but only for devices.

16.3.4. The Tunables tab

The **Tunables** tab contains **PowerTOP**'s suggestions for optimizing the system for lower power consumption.

Use the **up** and **down** keys to move through suggestions, and the **enter** key to toggle the suggestion on or off.

Figure 16.1. PowerTOP output

Additional resources

For more details on **PowerTOP**, see [PowerTOP's home page](#).

16.4. WHY POWERTOP DOES NOT DISPLAY FREQUENCY STATS VALUES IN SOME INSTANCES

While using the Intel P-State driver, PowerTOP only displays values in the **Frequency Stats** tab if the driver is in passive mode. But, even in this case, the values may be incomplete.

In total, there are three possible modes of the Intel P-State driver:

- Active mode with Hardware P-States (HWP)
- Active mode without HWP
- Passive mode

Switching to the ACPI CPUfreq driver results in complete information being displayed by PowerTOP. However, it is recommended to keep your system on the default settings.

To see what driver is loaded and in what mode, run:

```
# cat /sys/devices/system/cpu/cpu0/cpufreq/scaling_driver
```

- **intel_pstate** is returned if the Intel P-State driver is loaded and in active mode.
- **intel_cpufreq** is returned if the Intel P-State driver is loaded and in passive mode.
- **acpi-cpufreq** is returned if the ACPI CPUfreq driver is loaded.

While using the Intel P-State driver, add the following argument to the kernel boot command line to force the driver to run in passive mode:

```
intel_pstate=passive
```

To disable the Intel P-State driver and use, instead, the ACPI CPUfreq driver, add the following argument to the kernel boot command line:

```
intel_pstate=disable
```

16.5. GENERATING AN HTML OUTPUT

Apart from the **powertop's** output in terminal, you can also generate an HTML report.

Procedure

- Run the **powertop** command with the **--html** option:

```
# powertop --html=htmlfile.html
```

Replace the **htmlfile.html** parameter with the required name for the output file.

16.6. OPTIMIZING POWER CONSUMPTION

To optimize power consumption, you can use either the **powertop** service or the **powertop2tuned** utility.

16.6.1. Optimizing power consumption using the powertop service

You can use the **powertop** service to automatically enable all **PowerTOP**'s suggestions from the **Tunables** tab on the boot:

Procedure

- Enable the **powertop** service:

```
# systemctl enable powertop
```

16.6.2. The powertop2tuned utility

The **powertop2tuned** utility allows you to create custom **TuneD** profiles from **PowerTOP** suggestions.

By default, **powertop2tuned** creates profiles in the **/etc/tuned/** directory, and bases the custom profile on the currently selected **TuneD** profile. For safety reasons, all **PowerTOP** tunings are initially disabled in the new profile.

To enable the tunings, you can:

- Uncomment them in the **/etc/tuned/profile_name/tuned.conf** file.
- Use the **--enable** or **-e** option to generate a new profile that enables most of the tunings suggested by **PowerTOP**.
Certain potentially problematic tunings, such as the USB autosuspend, are disabled by default and need to be uncommented manually.

16.6.3. Optimizing power consumption using the powertop2tuned utility

Prerequisites

- The **powertop2tuned** utility is installed on the system:

```
# yum install tuned-utils
```

Procedure

1. Create a custom profile:

```
# powertop2tuned new_profile_name
```

2. Activate the new profile:

```
# tuned-adm profile new_profile_name
```

Additional information

- For a complete list of options that **powertop2tuned** supports, use:

```
$ powertop2tuned --help
```

16.6.4. Comparison of **powertop.service** and **powertop2tuned**

Optimizing power consumption with **powertop2tuned** is preferred over **powertop.service** for the following reasons:

- The **powertop2tuned** utility represents integration of **PowerTOP** into **TuneD**, which enables to benefit of advantages of both tools.
- The **powertop2tuned** utility allows for fine-grained control of enabled tuning.
- With **powertop2tuned**, potentially dangerous tuning are not automatically enabled.
- With **powertop2tuned**, rollback is possible without reboot.

CHAPTER 17. TUNING CPU FREQUENCY TO OPTIMIZE ENERGY CONSUMPTION

This section describes how to optimize the power consumption of your system by using the available **cpupower** commands to set CPU speed on a system as per your requirements after setting up the required CPUfreq governor.

17.1. SUPPORTED CPUPOWER TOOL COMMANDS

The **cpupower** tool is a collection of tools to examine and tune power saving related features of processors.

The **cpupower** tool supports the following commands:

idle-info

Displays the available idle states and other statistics for the CPU idle driver using the **cpupower idle-info** command. For more information, see [CPU Idle States](#).

idle-set

Enables or disables specific CPU idle state using the **cpupower idle-set** command as root. Use **-d** to disable and **-e** to enable a specific CPU idle state.

frequency-info

Displays the current **cpufreq** driver and available **cpufreq** governors using the **cpupower frequency-info** command. For more information, see [CPUfreq drivers](#), [Core CPUfreq Governors](#), and [Intel P-state CPUfreq governors](#).

frequency-set

Sets the **cpufreq** and governors using the **cpupower frequency-set** command as root. For more information, see [Setting up CPUfreq governor](#).

set

Sets processor power saving policies using the **cpupower set** command as root.

Using the **--perf-bias** option, you can enable software on supported Intel processors to determine the balance between optimum performance and saving power. Assigned values range from **0** to **15**, where **0** is optimum performance and **15** is optimum power efficiency. By default, the **--perf-bias** option applies to all cores. To apply it only to individual cores, add the **--cpu cpulist** option.

info

Displays processor power related and hardware configurations, which you have enabled using the **cpupower set** command. For example, if you assign the **--perf-bias** value as **5**:

```
# cpupower set --perf-bias 5
# cpupower info
analyzing CPU 0:
perf-bias: 5
```

monitor

Displays the idle statistics and CPU demands using the **cpupower monitor** command.

```
# cpupower monitor
| Nehalem    || Mperf  ||Idle_Stats
CPU| C3  | C6  | PC3  | PC6 || C0  | Cx  | Freq || POLL | C1  | C1E | C3  | C6  | C7s | C8  |
C9  | C10
```

```
0| 1.95| 55.12| 0.00| 0.00|| 4.21| 95.79| 3875|| 0.00| 0.68| 2.07| 3.39| 88.77| 0.00| 0.00|
0.00| 0.00
[...]
```

Using the **-l** option, you can list all available monitors on your system and the **-m** option to display information related to specific monitors. For example, to monitor information related to the **Mperf** monitor, use the **cpupower monitor -m Mperf** command as root.

Additional resources

- **cpupower(1)**, **cpupower-idle-info(1)**, **cpupower-idle-set(1)**, **cpupower-frequency-set(1)**, **cpupower-frequency-info(1)**, **cpupower-set(1)**, **cpupower-info(1)**, and **cpupower-monitor(1)** man pages

17.2. CPU IDLE STATES

CPUs with the x86 architecture support various states, such as, few parts of the CPU are deactivated or using lower performance settings, known as C-states.

With this state, you can save power by partially deactivating CPUs that are not in use. There is no need to configure the C-state, unlike P-states that require a governor and potentially some set up to avoid undesirable power or performance issues. C-states are numbered from C0 upwards, with higher numbers representing decreased CPU functionality and greater power saving. C-states of a given number are broadly similar across processors, although the exact details of the specific feature sets of the state may vary between processor families. C-states 0–3 are defined as follows:

C0

In this state, the CPU is working and not idle at all.

C1, Halt

In this state, the processor is not executing any instructions but is typically not in a lower power state. The CPU can continue processing with practically no delay. All processors offering C-states need to support this state. Pentium 4 processors support an enhanced C1 state called C1E that actually is a state for lower power consumption.

C2, Stop-Clock

In this state, the clock is frozen for this processor but it keeps the complete state for its registers and caches, so after starting the clock again it can immediately start processing again. This is an optional state.

C3, Sleep

In this state, the processor goes to sleep and does not need to keep its cache up to date. Due to this reason, waking up from this state needs considerably more time than from the C2 state. This is an optional state.

You can view the available idle states and other statistics for the CPUidle driver using the following command:

```
$ cpupower idle-info
CPUidle governor: menu
analyzing CPU 0:

Number of idle states: 9
Available idle states: POLL C1 C1E C3 C6 C7s C8 C9 C10
[...]
```

Intel CPUs with the "Nehalem" microarchitecture features a C6 state, which can reduce the voltage supply of a CPU to zero, but typically reduces power consumption by between 80% and 90%. The kernel in Red Hat Enterprise Linux 8 includes optimizations for this new C-state.

Additional resources

- **cpupower(1)** and **cpupower-idle(1)** man pages

17.3. OVERVIEW OF CPUFREQ

One of the most effective ways to reduce power consumption and heat output on your system is CPUfreq, which is supported by x86 and ARM64 architectures in Red Hat Enterprise Linux 8. CPUfreq, also referred to as CPU speed scaling, is the infrastructure in the Linux kernel that enables it to scale the CPU frequency in order to save power.

CPU scaling can be done automatically depending on the system load, in response to Advanced Configuration and Power Interface (ACPI) events, or manually by user-space programs, and it allows the clock speed of the processor to be adjusted on the fly. This enables the system to run at a reduced clock speed to save power. The rules for shifting frequencies, whether to a faster or slower clock speed and when to shift frequencies, are defined by the CPUfreq governor.

You can view the **cpufreq** information using the **cpupower frequency-info** command as root.

17.3.1. CPUfreq drivers

Using the **cpupower frequency-info --driver** command as root, you can view the current CPUfreq driver.

The following are the two available drivers for CPUfreq that can be used:

ACPI CPUfreq

Advanced Configuration and Power Interface (ACPI) CPUfreq driver is a kernel driver that controls the frequency of a particular CPU through ACPI, which ensures the communication between the kernel and the hardware.

Intel P-state

In Red Hat Enterprise Linux 8, Intel P-state driver is supported. The driver provides an interface for controlling the P-state selection on processors based on the Intel Xeon E series architecture or newer architectures.

Currently, Intel P-state is used by default for supported CPUs. You can switch to using ACPI CPUfreq by adding the **intel_pstate=disable** command to the kernel command line.

Intel P-state implements the **setpolicy()** callback. The driver decides what P-state to use based on the policy requested from the **cpufreq** core. If the processor is capable of selecting its next P-state internally, the driver offloads this responsibility to the processor. If not, the driver implements algorithms to select the next P-state.

Intel P-state provides its own **sysfs** files to control the P-state selection. These files are located in the **/sys/devices/system/cpu/intel_pstate/** directory. Any changes made to the files are applicable to all CPUs.

This directory contains the following files that are used for setting P-state parameters:

- **max_perf_pct** limits the maximum P-state requested by the driver expressed in a percentage of available performance. The available P-state performance can be reduced by the **no_turbo** setting.
- **min_perf_pct** limits the minimum P-state requested by the driver, expressed in a percentage of the maximum **no-turbo** performance level.
- **no_turbo** limits the driver to selecting P-state below the turbo frequency range.
- **turbo_pct** displays the percentage of the total performance supported by hardware that is in the turbo range. This number is independent of whether **turbo** has been disabled or not.
- **num_pstates** displays the number of P-states that are supported by hardware. This number is independent of whether turbo has been disabled or not.

Additional resources

- **cpupower-frequency-info(1)** man page

17.3.2. Core CPUfreq governors

A CPUfreq governor defines the power characteristics of the system CPU, which in turn affects the CPU performance. Each governor has its own unique behavior, purpose, and suitability in terms of workload. Using the **cpupower frequency-info --governor** command as root, you can view the available CPUfreq governors.

Red Hat Enterprise Linux 8 includes multiple core CPUfreq governors:

cpufreq_performance

It forces the CPU to use the highest possible clock frequency. This frequency is statically set and does not change. As such, this particular governor offers no power saving benefit. It is only suitable for hours of a heavy workload, and only during times wherein the CPU is rarely or never idle.

cpufreq_powersave

It forces the CPU to use the lowest possible clock frequency. This frequency is statically set and does not change. This governor offers maximum power savings, but at the cost of the lowest CPU performance. The term "powersave" can sometimes be deceiving though, since in principle a slow CPU on full load consumes more power than a fast CPU that is not loaded. As such, while it may be advisable to set the CPU to use the **powersave** governor during times of expected low activity, any unexpected high loads during that time can cause the system to actually consume more power. The Powersave governor is more of a speed limiter for the CPU than a power saver. It is most useful in systems and environments where overheating can be a problem.

cpufreq_ondemand

It is a dynamic governor, using which you can enable the CPU to achieve maximum clock frequency when the system load is high, and also minimum clock frequency when the system is idle. While this allows the system to adjust power consumption accordingly with respect to system load, it does so at the expense of latency between frequency switching. As such, latency can offset any performance or power saving benefits offered by the **ondemand** governor if the system switches between idle and heavy workloads too often. For most systems, the **ondemand** governor can provide the best compromise between heat emission, power consumption, performance, and manageability. When the system is only busy at specific times of the day, the **ondemand** governor automatically switches between maximum and minimum frequency depending on the load without any further intervention.

cpufreq_userspace

It allows user-space programs, or any process running as root, to set the frequency. Of all the governors, **userspace** is the most customizable and depending on how it is configured, it can offer the best balance between performance and consumption for your system.

cpufreq_conservative

Similar to the **ondemand** governor, the **conservative** governor also adjusts the clock frequency according to usage. However, the **conservative** governor switches between frequencies more gradually. This means that the **conservative** governor adjusts to a clock frequency that it considers best for the load, rather than simply choosing between maximum and minimum. While this can possibly provide significant savings in power consumption, it does so at an ever greater latency than the **ondemand** governor.

NOTE

You can enable a governor using **cron** jobs. This allows you to automatically set specific governors during specific times of the day. As such, you can specify a low-frequency governor during idle times, for example, after work hours, and return to a higher-frequency governor during hours of heavy workload.

For instructions on how to enable a specific governor, see [Setting up CPUfreq governor](#).

17.3.3. Intel P-state CPUfreq governors

By default, the Intel P-state driver operates in active mode with or without Hardware p-state (HWP) depending on whether the CPU supports HWP.

Using the **cpupower frequency-info --governor** command as root, you can view the available CPUfreq governors.

NOTE

The functionality of **performance** and **powersave** Intel P-state CPUfreq governors is different compared to core CPUfreq governors of the same names.

The Intel P-state driver can operate in the following three different modes:

Active mode with hardware-managed P-states

When active mode with HWP is used, the Intel P-state driver instructs the CPU to perform the P-state selection. The driver can provide frequency hints. However, the final selection depends on CPU internal logic. In active mode with HWP, the Intel P-state driver provides two P-state selection algorithms:

- **performance:** With the **performance** governor, the driver instructs internal CPU logic to be performance-oriented. The range of allowed P-states is restricted to the upper boundary of the range that the driver is allowed to use.
- **powersave:** With the **powersave** governor, the driver instructs internal CPU logic to be powersave-oriented.

Active mode without hardware-managed P-states

When active mode without HWP is used, the Intel P-state driver provides two P-state selection algorithms:

- **performance**: With the **performance** governor, the driver chooses the maximum P-state it is allowed to use.
- **powersave**: With the **powersave** governor, the driver chooses P-states proportional to the current CPU utilization. The behavior is similar to the **ondemand** CPUfreq core governor.

Passive mode

When the **passive** mode is used, the Intel P-state driver functions the same as the traditional CPUfreq scaling driver. All available generic CPUFreq core governors can be used.

17.3.4. Setting up CPUfreq governor

All CPUfreq drivers are built in as part of the **kernel-tools** package, and selected automatically. To set up CPUfreq, you need to select a governor.

Prerequisites

- To use **cpupower**, install the **kernel-tools** package:

```
# yum install kernel-tools
```

Procedure

1. View which governors are available for use for a specific CPU:

```
# cpupower frequency-info --governors
analyzing CPU 0:
available cpufreq governors: performance powersave
```

2. Enable one of the governors on all CPUs:

```
# cpupower frequency-set --governor performance
```

Replace the **performance** governor with the **cpufreq** governor name as per your requirement.

To only enable a governor on specific cores, use **-c** with a range or comma-separated list of CPU numbers. For example, to enable the **userspace** governor for CPUs 1-3 and 5, use:

```
# cpupower -c 1-3,5 frequency-set --governor cpufreq_userspace
```

NOTE

If the **kernel-tools** package is not installed, the CPUfreq settings can be viewed in the **/sys/devices/system/cpu/cpuid/cpufreq/** directory. Settings and values can be changed by writing to these tunables. For example, to set the minimum clock speed of cpu0 to 360 MHz, use:

```
# echo 360000 > /sys/devices/system/cpu/cpu0/cpufreq/scaling_min_freq
```

Verification

- Verify that the governor is enabled:

```
# cpupower frequency-info
analyzing CPU 0:
  driver: intel_pstate
  CPUs which run at the same hardware frequency: 0
  CPUs which need to have their frequency coordinated by software: 0
  maximum transition latency: Cannot determine or is not supported.
  hardware limits: 400 MHz - 4.20 GHz
  available cpufreq governors: performance powersave
  current policy: frequency should be within 400 MHz and 4.20 GHz.
    The governor "performance" may decide which speed to use within this range.
  current CPU frequency: Unable to call hardware
  current CPU frequency: 3.88 GHz (asserted by call to kernel)
  boost state support:
    Supported: yes
    Active: yes
```

The current policy displays the recently enabled **cpufreq** governor. In this case, it is ***performance***.

Additional resources

- **cpupower-frequency-info(1)** and **cpupower-frequency-set(1)** man pages

CHAPTER 18. GETTING STARTED WITH PERF

As a system administrator, you can use the **perf** tool to collect and analyze performance data of your system.

18.1. INTRODUCTION TO PERF

The **perf** user-space tool interfaces with the kernel-based subsystem *Performance Counters for Linux* (PCL). **perf** is a powerful tool that uses the Performance Monitoring Unit (PMU) to measure, record, and monitor a variety of hardware and software events. **perf** also supports tracepoints, kprobes, and uprobes.

18.2. INSTALLING PERF

This procedure installs the **perf** user-space tool.

Procedure

- Install the **perf** tool:

```
# yum install perf
```

18.3. COMMON PERF COMMANDS

This section provides an overview of commonly used **perf** commands.

Commonly used perf commands

perf stat

This command provides overall statistics for common performance events, including instructions executed and clock cycles consumed. Options allow for selection of events other than the default measurement events.

perf record

This command records performance data into a file, **perf.data**, which can be later analyzed using the **perf report** command.

perf report

This command reads and displays the performance data from the **perf.data** file created by **perf record**.

perf list

This command lists the events available on a particular machine. These events will vary based on performance monitoring hardware and software configuration of the system.

perf top

This command performs a similar function to the **top** utility. It generates and displays a performance counter profile in realtime.

perf trace

This command performs a similar function to the **strace** tool. It monitors the system calls used by a specified thread or process and all signals received by that application.

perf help

This command displays a complete list of **perf** commands.

Additional resources

- Add the **--help** option to a subcommand to open the man page.

CHAPTER 19. PROFILING CPU USAGE IN REAL TIME WITH PERF TOP

You can use the **perf top** command to measure CPU usage of different functions in real time.

Prerequisites

- You have the **perf** user space tool installed as described in [Installing perf](#).

19.1. THE PURPOSE OF PERF TOP

The **perf top** command is used for real time system profiling and functions similarly to the **top** utility. However, where the **top** utility generally shows you how much CPU time a given process or thread is using, **perf top** shows you how much CPU time each specific function uses. In its default state, **perf top** tells you about functions being used across all CPUs in both the user-space and the kernel-space. To use **perf top** you need root access.

19.2. PROFILING CPU USAGE WITH PERF TOP

This procedure activates **perf top** and profiles CPU usage in real time.

Prerequisites

- You have the **perf** user space tool installed as described in [Installing perf](#).
- You have root access

Procedure

- Start the **perf top** monitoring interface:

```
# perf top
```

The monitoring interface looks similar to the following:

```
-----
PerfTop: 20806 irq/s/sec kernel:57.3% exact: 100.0% lost: 0/0 drop: 0/0 [4000Hz cycles],
(all, 8 CPUs)
-----
Overhead Shared Object    Symbol
 2.20% [kernel]          [k] do_syscall_64
 2.17% [kernel]          [k] module_get_kallsym
 1.49% [kernel]          [k] copy_user_enhanced_fast_string
 1.37% libpthread-2.29.so [.] pthread_mutex_lock 1.31% [unknown] [.] 0000000000000000
 1.07% [kernel] [k] psi_task_change 1.04% [kernel] [k] switch_mm_irqs_off 0.94% [kernel] [k]
fget
 0.74% [kernel]          [k] entry_SYSCALL_64
 0.69% [kernel]          [k] syscall_return_via_sysret
 0.69% libxul.so          [.] 0x000000000113f9b0
 0.67% [kernel]          [k] kallsyms_expand_symbol.constprop.0
 0.65% firefox           [.] moz_xmalloc
 0.65% libpthread-2.29.so [.] __pthread_mutex_unlock_usercnt
 0.60% firefox           [.] free
```

0.60%	libxul.so	[.] 0x000000000241d1cd
0.60%	[kernel]	[k] do_sys_poll
0.58%	[kernel]	[k] menu_select
0.56%	[kernel]	[k] _raw_spin_lock_irqsave
0.55%	perf	[.] 0x00000000002ae0f3

In this example, the kernel function **do_syscall_64** is using the most CPU time.

Additional resources

- **perf-top(1)** man page

19.3. INTERPRETATION OF PERF TOP OUTPUT

The **perf top** monitoring interface displays the data in several columns:

The "Overhead" column

Displays the percent of CPU a given function is using.

The "Shared Object" column

Displays name of the program or library which is using the function.

The "Symbol" column

Displays the function name or symbol. Functions executed in the kernel-space are identified by **[k]** and functions executed in the user-space are identified by **[.]**.

19.4. WHY PERF DISPLAYS SOME FUNCTION NAMES AS RAW FUNCTION ADDRESSES

For kernel functions, **perf** uses the information from the **/proc/kallsyms** file to map the samples to their respective function names or symbols. For functions executed in the user space, however, you might see raw function addresses because the binary is stripped.

The **debuginfo** package of the executable must be installed or, if the executable is a locally developed application, the application must be compiled with debugging information turned on (the **-g** option in GCC) to display the function names or symbols in such a situation.

NOTE

It is not necessary to re-run the **perf record** command after installing the **debuginfo** associated with an executable. Simply re-run the **perf report** command.

Additional Resources

- [Enabling debugging with debugging information](#)

19.5. ENABLING DEBUG AND SOURCE REPOSITORIES

A standard installation of Red Hat Enterprise Linux does not enable the debug and source repositories. These repositories contain information needed to debug the system components and measure their performance.

Procedure

- Enable the source and debug information package channels:

```
# subscription-manager repos --enable rhel-8-for-$(uname -i)-baseos-debug-rpms
# subscription-manager repos --enable rhel-8-for-$(uname -i)-baseos-source-rpms
# subscription-manager repos --enable rhel-8-for-$(uname -i)-appstream-debug-rpms
# subscription-manager repos --enable rhel-8-for-$(uname -i)-appstream-source-rpms
```

The **\$(uname -i)** part is automatically replaced with a matching value for architecture of your system:

Architecture name	Value
64-bit Intel and AMD	x86_64
64-bit ARM	aarch64
IBM POWER	ppc64le
64-bit IBM Z	s390x

19.6. GETTING DEBUGINFO PACKAGES FOR AN APPLICATION OR LIBRARY USING GDB

Debugging information is required to debug code. For code that is installed from a package, the GNU Debugger (GDB) automatically recognizes missing debug information, resolves the package name and provides concrete advice on how to get the package.

Prerequisites

- The application or library you want to debug must be installed on the system.
- GDB and the **debuginfo-install** tool must be installed on the system. For details, see [Setting up to debug applications](#).
- Channels providing **debuginfo** and **debugsource** packages must be configured and enabled on the system.

Procedure

1. Start GDB attached to the application or library you want to debug. GDB automatically recognizes missing debugging information and suggests a command to run.

```
$ gdb -q /bin/ls
Reading symbols from /bin/ls...Reading symbols from .gnu_debugdata for /usr/bin/ls...(no
debugging symbols found)...done.
(no debugging symbols found)...done.
Missing separate debuginfos, use: dnf debuginfo-install coreutils-8.30-6.el8.x86_64
(gdb)
```

2. Exit GDB: type **q** and confirm with **Enter**.

```
(gdb) q
```

3. Run the command suggested by GDB to install the required **debuginfo** packages:

```
# dnf debuginfo-install coreutils-8.30-6.el8.x86_64
```

The **dnf** package management tool provides a summary of the changes, asks for confirmation and once you confirm, downloads and installs all the necessary files.

4. In case GDB is not able to suggest the **debuginfo** package, follow the procedure described in [Getting debuginfo packages for an application or library manually](#).

Additional resources

- [Red Hat Developer Toolset User Guide, section Installing Debugging Information](#)
- [How can I download or install debuginfo packages for RHEL systems?](#) – Red Hat Knowledgebase solution

CHAPTER 20. COUNTING EVENTS DURING PROCESS EXECUTION WITH PERF STAT

You can use the **perf stat** command to count hardware and software events during process execution.

Prerequisites

- You have the **perf** user space tool installed as described in [Installing perf](#).

20.1. THE PURPOSE OF PERF STAT

The **perf stat** command executes a specified command, keeps a running count of hardware and software event occurrences during the commands execution, and generates statistics of these counts. If you do not specify any events, then **perf stat** counts a set of common hardware and software events.

20.2. COUNTING EVENTS WITH PERF STAT

You can use **perf stat** to count hardware and software event occurrences during command execution and generate statistics of these counts. By default, **perf stat** operates in per-thread mode.

Prerequisites

- You have the **perf** user space tool installed as described in [Installing perf](#).

Procedure

- Count the events.
 - Running the **perf stat** command without root access will only count events occurring in the user space:

```
$ perf stat ls
```

Example 20.1. Output of perf stat ran without root access

```
Desktop Documents Downloads Music Pictures Public Templates Videos
```

```
Performance counter stats for 'ls':
```

```
1.28 msec task-clock:u          # 0.165 CPUs utilized
0      context-switches:u       # 0.000 M/sec
0      cpu-migrations:u        # 0.000 K/sec
104    page-faults:u           # 0.081 M/sec
1,054,302 cycles:u              # 0.823 GHz
1,136,989 instructions:u        # 1.08 insn per cycle
228,531 branches:u             # 178.447 M/sec
11,331 branch-misses:u         # 4.96% of all branches
```

```
0.007754312 seconds time elapsed
```

```
0.000000000 seconds user
```

```
0.007717000 seconds sys
```

■

As you can see in the previous example, when **perf stat** runs without root access the event names are followed by **:u**, indicating that these events were counted only in the user-space.

- To count both user-space and kernel-space events, you must have root access when running **perf stat**:

```
# perf stat ls
```

Example 20.2. Output of perf stat ran with root access

```
Desktop Documents Downloads Music Pictures Public Templates Videos
```

```
Performance counter stats for 'ls':
```

```

3.09 msec task-clock           # 0.119 CPUs utilized
18 context-switches           # 0.006 M/sec
3 cpu-migrations               # 0.969 K/sec
108 page-faults                # 0.035 M/sec
6,576,004 cycles                # 2.125 GHz
5,694,223 instructions          # 0.87 insn per cycle
1,092,372 branches              # 352.960 M/sec
31,515 branch-misses            # 2.89% of all branches
```

```
0.026020043 seconds time elapsed
```

```
0.000000000 seconds user
```

```
0.014061000 seconds sys
```

- By default, **perf stat** operates in per-thread mode. To change to CPU-wide event counting, pass the **-a** option to **perf stat**. To count CPU-wide events, you need root access:

```
# perf stat -a ls
```

Additional resources

- **perf-stat(1)** man page

20.3. INTERPRETATION OF PERF STAT OUTPUT

perf stat executes a specified command and counts event occurrences during the commands execution and displays statistics of these counts in three columns:

1. The number of occurrences counted for a given event
2. The name of the event that was counted
3. When related metrics are available, a ratio or percentage is displayed after the hash sign (**#**) in the right-most column.

For example, when running in default mode, **perf stat** counts both cycles and instructions and, therefore, calculates and displays instructions per cycle in the right-most column. You can see similar behavior with regard to branch-misses as a percent of all branches since both events are

counted by default.

20.4. ATTACHING PERF STAT TO A RUNNING PROCESS

You can attach **perf stat** to a running process. This will instruct **perf stat** to count event occurrences only in the specified processes during the execution of a command.

Prerequisites

- You have the **perf** user space tool installed as described in [Installing perf](#).

Procedure

- Attach **perf stat** to a running process:

```
$ perf stat -p ID1,ID2 sleep seconds
```

The previous example counts events in the processes with the IDs of ***ID1*** and ***ID2*** for a time period of ***seconds*** seconds as dictated by using the **sleep** command.

Additional resources

- **perf-stat(1)** man page

CHAPTER 21. RECORDING AND ANALYZING PERFORMANCE PROFILES WITH PERF

The **perf** tool allows you to record performance data and analyze it at a later time.

Prerequisites

- You have the **perf** user space tool installed as described in [Installing perf](#).

21.1. THE PURPOSE OF PERF RECORD

The **perf record** command samples performance data and stores it in a file, **perf.data**, which can be read and visualized with other **perf** commands. **perf.data** is generated in the current directory and can be accessed at a later time, possibly on a different machine.

If you do not specify a command for **perf record** to record during, it will record until you manually stop the process by pressing **Ctrl+C**. You can attach **perf record** to specific processes by passing the **-p** option followed by one or more process IDs. You can run **perf record** without root access, however, doing so will only sample performance data in the user space. In the default mode, **perf record** uses CPU cycles as the sampling event and operates in per-thread mode with inherit mode enabled.

21.2. RECORDING A PERFORMANCE PROFILE WITHOUT ROOT ACCESS

You can use **perf record** without root access to sample and record performance data in the user-space only.

Prerequisites

- You have the **perf** user space tool installed as described in [Installing perf](#).

Procedure

- Sample and record the performance data:

```
$ perf record command
```

Replace ***command*** with the command you want to sample data during. If you do not specify a command, then **perf record** will sample data until you manually stop it by pressing **Ctrl+C**.

Additional resources

- **perf-record(1)** man page

21.3. RECORDING A PERFORMANCE PROFILE WITH ROOT ACCESS

You can use **perf record** with root access to sample and record performance data in both the user-space and the kernel-space simultaneously.

Prerequisites

- You have the **perf** user space tool installed as described in [Installing perf](#).

- You have root access.

Procedure

- Sample and record the performance data:

```
# perf record command
```

Replace ***command*** with the command you want to sample data during. If you do not specify a command, then **perf record** will sample data until you manually stop it by pressing **Ctrl+C**.

Additional resources

- **perf-record(1)** man page

21.4. RECORDING A PERFORMANCE PROFILE IN PER-CPU MODE

You can use **perf record** in per-CPU mode to sample and record performance data in both user-space and the kernel-space simultaneously across all threads on a monitored CPU. By default, per-CPU mode monitors all online CPUs.

Prerequisites

- You have the **perf** user space tool installed as described in [Installing perf](#).

Procedure

- Sample and record the performance data:

```
# perf record -a command
```

Replace ***command*** with the command you want to sample data during. If you do not specify a command, then **perf record** will sample data until you manually stop it by pressing **Ctrl+C**.

Additional resources

- **perf-record(1)** man page

21.5. CAPTURING CALL GRAPH DATA WITH PERF RECORD

You can configure the **perf record** tool so that it records which function is calling other functions in the performance profile. This helps to identify a bottleneck if several processes are calling the same function.

Prerequisites

- The **perf** user space tool is installed. For more information, see [Installing perf](#).

Procedure

- Sample and record performance data with the **--call-graph** option:

```
$ perf record --call-graph method command
```

- Replace **command** with the command you want to sample data during. If you do not specify a command, then **perf record** will sample data until you manually stop it by pressing **Ctrl+C**.
- Replace *method* with one of the following unwinding methods:

fp

Uses the frame pointer method. Depending on compiler optimization, such as with binaries built with the GCC option **--fomit-frame-pointer**, this may not be able to unwind the stack.

dwarf

Uses DWARF Call Frame Information to unwind the stack.

lbr

Uses the last branch record hardware on Intel processors.

Additional resources

- **perf-record(1)** man page

21.6. ANALYZING PERF.DATA WITH PERF REPORT

You can use **perf report** to display and analyze a **perf.data** file.

Prerequisites

- The **perf** user space tool is installed. For more information, see [Installing perf](#).
- There is a **perf.data** file in the current directory.
- If the **perf.data** file was created with root access, you need to run **perf report** with root access too.

Procedure

- Display the contents of the **perf.data** file for further analysis:

```
# perf report
```

This command displays output similar to the following:

```
Samples: 2K of event 'cycles', Event count (approx.): 235462960
Overhead Command      Shared Object          Symbol
 2.36% kswapd0          [kernel.kallsyms]      [k] page_vma_mapped_walk
 2.13% sssd_kcm          libc-2.28.so            [.] memset_avx2_erms 2.13% perf
[kernel.kallsyms] [k] smp_call_function_single 1.53% gnome-shell libc-2.28.so [.]
strcmp_avx2
 1.17% gnome-shell      libglib-2.0.so.0.5600.4 [.] g_hash_table_lookup
 0.93% Xorg              libc-2.28.so            [.] memmove_avx_unaligned_erms 0.89%
gnome-shell libgobject-2.0.so.0.5600.4 [.] g_object_unref 0.87% kswapd0 [kernel.kallsyms]
[k] page_referenced_one 0.86% gnome-shell libc-2.28.so [.] memmove_avx_unaligned_erms
 0.83% Xorg              [kernel.kallsyms]      [k] alloc_vmap_area
 0.63% gnome-shell      libglib-2.0.so.0.5600.4 [.] g_slice_alloc
 0.53% gnome-shell      libgirepository-1.0.so.1.0.0 [.] g_base_info_unref
```

```

0.53% gnome-shell ld-2.28.so      [.] _dl_find_dso_for_object
0.49% kswapd0      [kernel.kallsyms]      [k] vma_interval_tree_iter_next
0.48% gnome-shell libpthread-2.28.so      [.] pthread_getspecific 0.47% gnome-
shell libgirepository-1.0.so.1.0.0 [.] 0x00000000000013b1d 0.45% gnome-shell libglib-
2.0.so.0.5600.4 [.] g_slice_free1 0.45% gnome-shell libgobject-2.0.so.0.5600.4 [.]
g_type_check_instance_is_fundamentally_a 0.44% gnome-shell libc-2.28.so [.] malloc 0.41%
swapper [kernel.kallsyms] [k] apic_timer_interrupt 0.40% gnome-shell ld-2.28.so [.]
_dl_lookup_symbol_x 0.39% kswapd0 [kernel.kallsyms] [k]
raw_callee_save___pv_queued_spin_unlock

```

Additional resources

- **perf-report(1)** man page

21.7. INTERPRETATION OF PERF REPORT OUTPUT

The table displayed by running the **perf report** command sorts the data into several columns:

The 'Overhead' column

Indicates what percentage of overall samples were collected in that particular function.

The 'Command' column

Tells you which process the samples were collected from.

The 'Shared Object' column

Displays the name of the ELF image where the samples come from (the name `[kernel.kallsyms]` is used when the samples come from the kernel).

The 'Symbol' column

Displays the function name or symbol.

In default mode, the functions are sorted in descending order with those with the highest overhead displayed first.

21.8. GENERATING A PERF.DATA FILE THAT IS READABLE ON A DIFFERENT DEVICE

You can use the **perf** tool to record performance data into a **perf.data** file to be analyzed on a different device.

Prerequisites

- You have the **perf** user space tool installed as described in [Installing perf](#).
- The kernel **debuginfo** package is installed. For more information, see [Getting debuginfo packages for an application or library using GDB](#).

Procedure

1. Capture performance data you are interested in investigating further:

```
# perf record -a --call-graph fp sleep seconds
```

This example would generate a **perf.data** over the entire system for a period of **seconds** seconds as dictated by the use of the **sleep** command. It would also capture call graph data using the frame pointer method.

2. Generate an archive file containing debug symbols of the recorded data:

```
# perf archive
```

Verification steps

- Verify that the archive file has been generated in your current active directory:

```
# ls perf.data*
```

The output will display every file in your current directory that begins with **perf.data**. The archive file will be named either:

```
perf.data.tar.gz
```

or

```
perf.data.tar.bz2
```

Additional resources

- [Recording and analyzing performance profiles with perf](#)
- [Capturing call graph data with perf record](#)

21.9. ANALYZING A PERF.DATA FILE THAT WAS CREATED ON A DIFFERENT DEVICE

You can use the **perf** tool to analyze a **perf.data** file that was generated on a different device.

Prerequisites

- You have the **perf** user space tool installed as described in [Installing perf](#).
- A **perf.data** file and associated archive file generated on a different device are present on the current device being used.

Procedure

1. Copy both the **perf.data** file and the archive file into your current active directory.
2. Extract the archive file into **~/debug**:

```
# mkdir -p ~/debug
# tar xf perf.data.tar.bz2 -C ~/debug
```

**NOTE**

The archive file might also be named ***perf.data.tar.gz***.

3. Open the **perf.data** file for further analysis:

```
# perf report
```

21.10. WHY PERF DISPLAYS SOME FUNCTION NAMES AS RAW FUNCTION ADDRESSES

For kernel functions, **perf** uses the information from the **/proc/kallsyms** file to map the samples to their respective function names or symbols. For functions executed in the user space, however, you might see raw function addresses because the binary is stripped.

The **debuginfo** package of the executable must be installed or, if the executable is a locally developed application, the application must be compiled with debugging information turned on (the **-g** option in GCC) to display the function names or symbols in such a situation.

**NOTE**

It is not necessary to re-run the **perf record** command after installing the **debuginfo** associated with an executable. Simply re-run the **perf report** command.

Additional Resources

- [Enabling debugging with debugging information](#)

21.11. ENABLING DEBUG AND SOURCE REPOSITORIES

A standard installation of Red Hat Enterprise Linux does not enable the debug and source repositories. These repositories contain information needed to debug the system components and measure their performance.

Procedure

- Enable the source and debug information package channels:

```
# subscription-manager repos --enable rhel-8-for-$(uname -i)-baseos-debug-rpms
# subscription-manager repos --enable rhel-8-for-$(uname -i)-baseos-source-rpms
# subscription-manager repos --enable rhel-8-for-$(uname -i)-appstream-debug-rpms
# subscription-manager repos --enable rhel-8-for-$(uname -i)-appstream-source-rpms
```

The **\$(uname -i)** part is automatically replaced with a matching value for architecture of your system:

Architecture name	Value
64-bit Intel and AMD	x86_64
64-bit ARM	aarch64

Architecture name	Value
IBM POWER	ppc64le
64-bit IBM Z	s390x

21.12. GETTING DEBUGINFO PACKAGES FOR AN APPLICATION OR LIBRARY USING GDB

Debugging information is required to debug code. For code that is installed from a package, the GNU Debugger (GDB) automatically recognizes missing debug information, resolves the package name and provides concrete advice on how to get the package.

Prerequisites

- The application or library you want to debug must be installed on the system.
- GDB and the **debuginfo-install** tool must be installed on the system. For details, see [Setting up to debug applications](#).
- Channels providing **debuginfo** and **debugsource** packages must be configured and enabled on the system.

Procedure

1. Start GDB attached to the application or library you want to debug. GDB automatically recognizes missing debugging information and suggests a command to run.

```
$ gdb -q /bin/ls
Reading symbols from /bin/ls...Reading symbols from .gnu_debugdata for /usr/bin/ls...(no
debugging symbols found)...done.
(no debugging symbols found)...done.
Missing separate debuginfos, use: dnf debuginfo-install coreutils-8.30-6.el8.x86_64
(gdb)
```

2. Exit GDB: type **q** and confirm with **Enter**.

```
(gdb) q
```

3. Run the command suggested by GDB to install the required **debuginfo** packages:

```
# dnf debuginfo-install coreutils-8.30-6.el8.x86_64
```

The **dnf** package management tool provides a summary of the changes, asks for confirmation and once you confirm, downloads and installs all the necessary files.

4. In case GDB is not able to suggest the **debuginfo** package, follow the procedure described in [Getting debuginfo packages for an application or library manually](#).

Additional resources

- [Red Hat Developer Toolset User Guide, section Installing Debugging Information](#)
- [How can I download or install debuginfo packages for RHEL systems? – Red Hat Knowledgebase solution](#)

CHAPTER 22. INVESTIGATING BUSY CPUS WITH PERF

When investigating performance issues on a system, you can use the **perf** tool to identify and monitor the busiest CPUs in order to focus your efforts.

22.1. DISPLAYING WHICH CPU EVENTS WERE COUNTED ON WITH PERF STAT

You can use **perf stat** to display which CPU events were counted on by disabling CPU count aggregation. You must count events in system-wide mode by using the **-a** flag in order to use this functionality.

Prerequisites

- You have the **perf** user space tool installed as described in [Installing perf](#).

Procedure

- Count the events with CPU count aggregation disabled:

```
# perf stat -a -A sleep seconds
```

The previous example displays counts of a default set of common hardware and software events recorded over a time period of ***seconds*** seconds, as dictated by using the **sleep** command, over each individual CPU in ascending order, starting with **CPU0**. As such, it may be useful to specify an event such as cycles:

```
# perf stat -a -A -e cycles sleep seconds
```

22.2. DISPLAYING WHICH CPU SAMPLES WERE TAKEN ON WITH PERF REPORT

The **perf record** command samples performance data and stores this data in a **perf.data** file which can be read with the **perf report** command. The **perf record** command always records which CPU samples were taken on. You can configure **perf report** to display this information.

Prerequisites

- You have the **perf** user space tool installed as described in [Installing perf](#).
- There is a **perf.data** file created with **perf record** in the current directory. If the **perf.data** file was created with root access, you need to run **perf report** with root access too.

Procedure

- Display the contents of the **perf.data** file for further analysis while sorting by CPU:

```
# perf report --sort cpu
```

- You can sort by CPU and command to display more detailed information about where CPU time is being spent:

```
# perf report --sort cpu,comm
```

This example will list commands from all monitored CPUs by total overhead in descending order of overhead usage and identify the CPU the command was executed on.

Additional resources

- [Recording and analyzing performance profiles with perf](#)

22.3. DISPLAYING SPECIFIC CPUS DURING PROFILING WITH PERF TOP

You can configure **perf top** to display specific CPUs and their relative usage while profiling your system in real time.

Prerequisites

- You have the **perf** user space tool installed as described in [Installing perf](#).

Procedure

- Start the **perf top** interface while sorting by CPU:

```
# perf top --sort cpu
```

This example will list CPUs and their respective overhead in descending order of overhead usage in real time.

- You can sort by CPU and command for more detailed information of where CPU time is being spent:

```
# perf top --sort cpu,comm
```

This example will list commands by total overhead in descending order of overhead usage and identify the CPU the command was executed on in real time.

22.4. MONITORING SPECIFIC CPUS WITH PERF RECORD AND PERF REPORT

You can configure **perf record** to only sample specific CPUs of interest and analyze the generated **perf.data** file with **perf report** for further analysis.

Prerequisites

- You have the **perf** user space tool installed as described in [Installing perf](#).

Procedure

1. Sample and record the performance data in the specific CPU's, generating a **perf.data** file:
 - Using a comma separated list of CPUs:

```
# perf record -C 0,1 sleep seconds
```

The previous example samples and records data in CPUs 0 and 1 for a period of **seconds** seconds as dictated by the use of the **sleep** command.

- Using a range of CPUs:

```
# perf record -C 0-2 sleep seconds
```

The previous example samples and records data in all CPUs from CPU 0 to 2 for a period of **seconds** seconds as dictated by the use of the **sleep** command.

2. Display the contents of the **perf.data** file for further analysis:

```
# perf report
```

This example will display the contents of **perf.data**. If you are monitoring several CPUs and want to know which CPU data was sampled on, see [Displaying which CPU samples were taken on with perf report](#).

CHAPTER 23. MONITORING APPLICATION PERFORMANCE WITH PERF

This section describes how to use the **perf** tool to monitor application performance.

23.1. ATTACHING PERF RECORD TO A RUNNING PROCESS

You can attach **perf record** to a running process. This will instruct **perf record** to only sample and record performance data in the specified processes.

Prerequisites

- The **perf** user space tool is installed. For more information, see [Installing perf](#).

Procedure

- Attach **perf record** to a running process:

```
$ perf record -p ID1,ID2 sleep seconds
```

The previous example samples and records performance data of the processes with the process ID's **ID1** and **ID2** for a time period of **seconds** seconds as dictated by using the **sleep** command. You can also configure **perf** to record events in specific threads:

```
$ perf record -t ID1,ID2 sleep seconds
```

NOTE

When using the **-t** flag and stipulating thread ID's, **perf** disables inheritance by default. You can enable inheritance by adding the **--inherit** option.

23.2. CAPTURING CALL GRAPH DATA WITH PERF RECORD

You can configure the **perf record** tool so that it records which function is calling other functions in the performance profile. This helps to identify a bottleneck if several processes are calling the same function.

Prerequisites

- The **perf** user space tool is installed. For more information, see [Installing perf](#).

Procedure

- Sample and record performance data with the **--call-graph** option:

```
$ perf record --call-graph method command
```

- Replace **command** with the command you want to sample data during. If you do not specify a command, then **perf record** will sample data until you manually stop it by pressing **Ctrl+C**.
- Replace **method** with one of the following unwinding methods:

• **libunwind**

ip

Uses the frame pointer method. Depending on compiler optimization, such as with binaries built with the GCC option **--fomit-frame-pointer**, this may not be able to unwind the stack.

dwarf

Uses DWARF Call Frame Information to unwind the stack.

lbr

Uses the last branch record hardware on Intel processors.

Additional resources

- **perf-record(1)** man page

23.3. ANALYZING PERF.DATA WITH PERF REPORT

You can use **perf report** to display and analyze a **perf.data** file.

Prerequisites

- The **perf** user space tool is installed. For more information, see [Installing perf](#).
- There is a **perf.data** file in the current directory.
- If the **perf.data** file was created with root access, you need to run **perf report** with root access too.

Procedure

- Display the contents of the **perf.data** file for further analysis:

```
# perf report
```

This command displays output similar to the following:

```
Samples: 2K of event 'cycles', Event count (approx.): 235462960
Overhead Command      Shared Object      Symbol
 2.36% kswapd0      [kernel.kallsyms]  [k] page_vma_mapped_walk
 2.13% sssd_kcm      libc-2.28.so        [.] memset_avx2_erms 2.13% perf
[kernel.kallsyms] [k] smp_call_function_single 1.53% gnome-shell libc-2.28.so [.]
strcmp_avx2
 1.17% gnome-shell  libglib-2.0.so.0.5600.4 [.] g_hash_table_lookup
 0.93% Xorg          libc-2.28.so        [.] memmove_avx_unaligned_erms 0.89%
gnome-shell libgobject-2.0.so.0.5600.4 [.] g_object_unref 0.87% kswapd0 [kernel.kallsyms]
[k] page_referenced_one 0.86% gnome-shell libc-2.28.so [.] memmove_avx_unaligned_erms
 0.83% Xorg          [kernel.kallsyms]  [k] alloc_vmap_area
 0.63% gnome-shell  libglib-2.0.so.0.5600.4 [.] g_slice_alloc
 0.53% gnome-shell  libgirepository-1.0.so.1.0.0 [.] g_base_info_unref
 0.53% gnome-shell  ld-2.28.so          [.] dl_find_dso_for_object
 0.49% kswapd0      [kernel.kallsyms]  [k] vma_interval_tree_iter_next
 0.48% gnome-shell  libpthread-2.28.so  [.] pthread_getspecific 0.47% gnome-
shell libgirepository-1.0.so.1.0.0 [.] 0x0000000000013b1d 0.45% gnome-shell libglib-
2.0.so.0.5600.4 [.] g_slice_free1 0.45% gnome-shell libgobject-2.0.so.0.5600.4 [.]
g_type_check_instance_is_fundamentally_a 0.44% gnome-shell libc-2.28.so [.] malloc 0.41%
```

```
swapper [kernel.kallsyms] [k] apic_timer_interrupt 0.40% gnome-shell ld-2.28.so [.]  
_dl_lookup_symbol_x 0.39% kswapd0 [kernel.kallsyms] [k]  
raw_callee_save___pv_queued_spin_unlock
```

Additional resources

- **perf-report(1)** man page

CHAPTER 24. CREATING UPROBES WITH PERF

24.1. CREATING UPROBES AT THE FUNCTION LEVEL WITH PERF

You can use the **perf** tool to create dynamic tracepoints at arbitrary points in a process or application. These tracepoints can then be used in conjunction with other **perf** tools such as **perf stat** and **perf record** to better understand the process or applications behavior.

Prerequisites

- You have the **perf** user space tool installed as described in [Installing perf](#).

Procedure

1. Create the uprobe in the process or application you are interested in monitoring at a location of interest within the process or application:

```
# perf probe -x /path/to/executable -a function
Added new event:
  probe_executable:function (on function in /path/to/executable)
```

You can now use it in all perf tools, such as:

```
perf record -e probe_executable:function -aR sleep 1
```

Additional resources

- **perf-probe** man page
- [Recording and analyzing performance profiles with perf](#)
- [Counting events during process execution with perf stat](#)

24.2. CREATING UPROBES ON LINES WITHIN A FUNCTION WITH PERF

These tracepoints can then be used in conjunction with other **perf** tools such as **perf stat** and **perf record** to better understand the process or applications behavior.

Prerequisites

- You have the **perf** user space tool installed as described in [Installing perf](#).
- You have gotten the debugging symbols for your executable:

```
# objdump -t ./your_executable | head
```

NOTE

To do this, the **debuginfo** package of the executable must be installed or, if the executable is a locally developed application, the application must be compiled with debugging information, the **-g** option in GCC.

Procedure

1. View the function lines where you can place a uprobe:

```
$ perf probe -x ./your_executable -L main
```

Output of this command looks similar to:

```
<main@/home/user/my_executable:0>
  0 int main(int argc, const char **argv)
  1 {
      int err;
      const char *cmd;
      char sbuf[STRERR_BUFSIZE];

      /* libsubcmd init */
  7   exec_cmd_init("perf", PREFIX, PERF_EXEC_PATH,
EXEC_PATH_ENVIRONMENT);
  8   pager_init(PERF_PAGER_ENVIRONMENT);
```

2. Create the uprobe for the desired function line:

```
# perf probe -x ./my_executable main:8
Added new event:
  probe_my_executable:main_L8 (on main:8 in /home/user/my_executable)
```

You can now use it in all perf tools, such as:

```
perf record -e probe_my_executable:main_L8 -aR sleep 1
```

24.3. PERF SCRIPT OUTPUT OF DATA RECORDED OVER UPROBES

A common method to analyze data collected using uprobes is using the **perf script** command to read a **perf.data** file and display a detailed trace of the recorded workload.

In the perf script example output: * A uprobe is added to the function **isprime()** in a program called **my_prog** * **a** is a function argument added to the uprobe. Alternatively, **a** could be an arbitrary variable visible in the code scope of where you add your uprobe:

```
# perf script
my_prog 1367 [007] 10802159.906593: probe_my_prog:isprime: (400551) a=2
my_prog 1367 [007] 10802159.906623: probe_my_prog:isprime: (400551) a=3
my_prog 1367 [007] 10802159.906625: probe_my_prog:isprime: (400551) a=4
my_prog 1367 [007] 10802159.906627: probe_my_prog:isprime: (400551) a=5
my_prog 1367 [007] 10802159.906629: probe_my_prog:isprime: (400551) a=6
my_prog 1367 [007] 10802159.906631: probe_my_prog:isprime: (400551) a=7
my_prog 1367 [007] 10802159.906633: probe_my_prog:isprime: (400551) a=13
my_prog 1367 [007] 10802159.906635: probe_my_prog:isprime: (400551) a=17
my_prog 1367 [007] 10802159.906637: probe_my_prog:isprime: (400551) a=19
```

CHAPTER 25. PROFILING MEMORY ACCESSSES WITH PERF MEM

You can use the **perf mem** command to sample memory accesses on your system.

25.1. THE PURPOSE OF PERF MEM

The **mem** subcommand of the **perf** tool enables the sampling of memory accesses (loads and stores). The **perf mem** command provides information about memory latency, types of memory accesses, functions causing cache hits and misses, and, by recording the data symbol, the memory locations where these hits and misses occur.

25.2. SAMPLING MEMORY ACCESS WITH PERF MEM

This procedure describes how to use the **perf mem** command to sample memory accesses on your system. The command takes the same options as **perf record** and **perf report** as well as some options exclusive to the **mem** subcommand. The recorded data is stored in a **perf.data** file in the current directory for later analysis.

Prerequisites

- The **perf** user space tool is installed. For more information, see [Installing perf](#).

Procedure

1. Sample the memory accesses:

```
# perf mem record -a sleep seconds
```

This example samples memory accesses across all CPUs for a period of *seconds* seconds as dictated by the **sleep** command. You can replace the **sleep** command for any command during which you want to sample memory access data. By default, **perf mem** samples both memory loads and stores. You can select only one memory operation by using the **-t** option and specifying either "load" or "store" between **perf mem** and **record**. For loads, information over the memory hierarchy level, TLB memory accesses, bus snoops, and memory locks is captured.

2. Open the **perf.data** file for analysis:

```
# perf mem report
```

If you have used the example commands, the output is:

```
Available samples
35k cpu/mem-loads,ldlat=30/P
54k cpu/mem-stores/P
```

The **cpu/mem-loads,ldlat=30/P** line denotes data collected over memory loads and the **cpu/mem-stores/P** line denotes data collected over memory stores. Highlight the category of interest and press **Enter** to view the data:

```
Samples: 35K of event 'cpu/mem-loads,ldlat=30/P', Event count (approx.): 4067062
Overhead    Samples Local Weight Memory access      Symbol
```

Shared Object		Data Symbol	Data Object

Alternatively, you can sort your results to investigate different aspects of interest when displaying the data. For example, to sort data over memory loads by type of memory accesses occurring during the sampling period in descending order of overhead they account for:

```
# perf mem -t load report --sort=mem
```

For example, the output can be:

```
Samples: 35K of event 'cpu/mem-loads,ldlat=30/P', Event count (approx.): 40670
Overhead   Samples  Memory access
31.53%     9725   LFB or LFB hit
29.70%    12201  L1 or L1 hit
23.03%     9725   L3 or L3 hit
12.91%     2316   Local RAM or RAM hit
 2.37%      743   L2 or L2 hit
 0.34%        9   Uncached or N/A hit
 0.10%       69   I/O or N/A hit
 0.02%      825   L3 miss
```

Additional resources

- **perf-mem(1)** man page.

25.3. INTERPRETATION OF PERF MEM REPORT OUTPUT

The table displayed by running the **perf mem report** command without any modifiers sorts the data into several columns:

The 'Overhead' column

Indicates percentage of overall samples collected in that particular function.

The 'Samples' column

Displays the number of samples accounted for by that row.

The 'Local Weight' column

Displays the access latency in processor core cycles.

The 'Memory Access' column

Displays the type of memory access that occurred.

The 'Symbol' column

Displays the function name or symbol.

The 'Shared Object' column

Displays the name of the ELF image where the samples come from (the name [kernel.kallsyms] is used when the samples come from the kernel).

The 'Data Symbol' column

Displays the address of the memory location that row was targeting.

IMPORTANT

Oftentimes, due to dynamic allocation of memory or stack memory being accessed, the 'Data Symbol' column will display a raw address.

The "Snoop" column

Displays bus transactions.

The 'TLB Access' column

Displays TLB memory accesses.

The 'Locked' column

Indicates if a function was or was not memory locked.

In default mode, the functions are sorted in descending order with those with the highest overhead displayed first.

CHAPTER 26. DETECTING FALSE SHARING

False sharing occurs when a processor core on a Symmetric Multi Processing (SMP) system modifies data items on the same cache line that is in use by other processors to access other data items that are not being shared between the processors.

This initial modification requires that the other processors using the cache line invalidate their copy and request an updated one despite the processors not needing, or even necessarily having access to, an updated version of the modified data item.

You can use the **perf c2c** command to detect false sharing.

26.1. THE PURPOSE OF PERF C2C

The **c2c** subcommand of the **perf** tool enables Shared Data Cache-to-Cache (C2C) analysis. You can use the **perf c2c** command to inspect cache-line contention to detect both true and false sharing.

Cache-line contention occurs when a processor core on a Symmetric Multi Processing (SMP) system modifies data items on the same cache line that is in use by other processors. All other processors using this cache-line must then invalidate their copy and request an updated one. This can lead to degraded performance.

The **perf c2c** command provides the following information:

- Cache lines where contention has been detected
- Processes reading and writing the data
- Instructions causing the contention
- The Non-Uniform Memory Access (NUMA) nodes involved in the contention

26.2. DETECTING CACHE-LINE CONTENTION WITH PERF C2C

Use the **perf c2c** command to detect cache-line contention in a system.

The **perf c2c** command supports the same options as **perf record** as well as some options exclusive to the **c2c** subcommand. The recorded data is stored in a **perf.data** file in the current directory for later analysis.

Prerequisites

- The **perf** user space tool is installed. For more information, see [installing perf](#).

Procedure

- Use **perf c2c** to detect cache-line contention:

```
# perf c2c record -a sleep seconds
```

This example samples and records cache-line contention data across all CPU's for a period of **seconds** as dictated by the **sleep** command. You can replace the **sleep** command with any command you want to collect cache-line contention data over.

Additional resources

- **perf-c2c(1)** man page

26.3. VISUALIZING A PERF.DATA FILE RECORDED WITH PERF C2C RECORD

This procedure describes how to visualize the **perf.data** file, which is recorded using the **perf c2c** command.

Prerequisites

- The **perf** user space tool is installed. For more information, see [installing perf](#).
- A **perf.data** file recorded using the **perf c2c** command is available in the current directory. For more information, see [Detecting cache-line contention with perf c2c](#).

Procedure

1. Open the **perf.data** file for further analysis:

```
# perf c2c report --stdio
```

This command visualizes the **perf.data** file into several graphs within the terminal:

```

26.4. INTERPRETATION OF PERF C2C REPORT OUTPUT

This section describes how to interpret the output of the **perf c2c report** command.

The visualization displayed by running the **perf c2c report --stdio** command sorts the data into several tables:

Trace Events Information

This table provides a high level summary of all the load and store samples, which are collected by the **perf c2c record** command.

Global Shared Cache Line Event Information

This table provides statistics over the shared cache lines.

c2c Details

This table provides information about what events were sampled and how the **perf c2c report** data is organized within the visualization.

Shared Data Cache Line Table

This table provides a one line summary for the hottest cache lines where false sharing is detected and is sorted in descending order by the amount of remote **Hitm** detected per cache line by default.

Shared Cache Line Distribution Pareto

This tables provides a variety of information about each cache line experiencing contention:

- The cache lines are numbered in the **NUM** column, starting at **0**.
- The virtual address of each cache line is contained in the **Data address Offset** column and followed subsequently by the offset into the cache line where different accesses occurred.
- The **Pid** column contains the process ID.
- The **Code Address** column contains the instruction pointer code address.
- The columns under the **cycles** label show average load latencies.
- The **cpu cnt** column displays how many different CPUs samples came from (essentially, how many different CPUs were waiting for the data indexed at that given location).
- The **Symbol** column displays the function name or symbol.
- The **Shared Object** column displays the name of the ELF image where the samples come from (the name **[kernel.kallsyms]** is used when the samples come from the kernel).
- The **Source:Line** column displays the source file and line number.
- The **Node{cpu list}** column displays which specific CPUs samples came from for each node.

26.5. DETECTING FALSE SHARING WITH PERF C2C

This procedure describes how to detect false sharing using the **perf c2c** command.

Prerequisites

- The **perf** user space tool is installed. For more information, see [installing perf](#).
- A **perf.data** file recorded using the **perf c2c** command is available in the current directory. For more information, see [Detecting cache-line contention with perf c2c](#).

Procedure

1. Open the **perf.data** file for further analysis:

```
# perf c2c report --stdio
```

This opens the **perf.data** file in the terminal.

2. In the "Trace Event Information" table, locate the row containing the values for **LLC Misses to Remote Cache (HITM)**:

The percentage in the value column of the **LLC Misses to Remote Cache (HITM)** row represents the percentage of LLC misses that were occurring across NUMA nodes in modified cache-lines and is a key indicator false sharing has occurred.

■

```

2 0xffff883ffb6a7e80 260 0.09% 15 3 12 161 161 0 1
1 15 99 25 50 0 6 1
3 0xffffffff81aec000 157 0.07% 9 0 9 1 0 1 0 7

```

20	156	50	59	0	27	4									
	4	0xffffffff	81e3f540	179	0.06%	9	1	8	117	97	20	0			
10	25	62	11	1	0	24	7								

This table is sorted in descending order by the amount of remote **Hitm** detected per cache line. A high number in the **Rmt** column of the **LLC Load Hitm** section indicates false sharing and requires further inspection of the cache line on which it occurred to debug the false sharing activity.

CHAPTER 27. GETTING STARTED WITH FLAMEGRAPHS

As a system administrator, you can use **flamegraphs** to create visualizations of system performance data recorded with the **perf** tool. As a software developer, you can use **flamegraphs** to create visualizations of application performance data recorded with the **perf** tool.

Sampling stack traces is a common technique for profiling CPU performance with the **perf** tool. Unfortunately, the results of profiling stack traces with **perf** can be extremely verbose and labor-intensive to analyze. **flamegraphs** are visualizations created from data recorded with **perf** to make identifying hot code-paths faster and easier.

27.1. INSTALLING FLAMEGRAPHS

To begin using **flamegraphs**, install the required package.

Procedure

- Install the **flamegraphs** package:

```
# yum install js-d3-flame-graph
```

27.2. CREATING FLAMEGRAPHS OVER THE ENTIRE SYSTEM

This procedure describes how to visualize performance data recorded over an entire system using **flamegraphs**.

Prerequisites

- **flamegraphs** are installed as described in [installing flamegraphs](#).
- The **perf** tool is installed as described in [installing perf](#).

Procedure

- Record the data and create the visualization:

```
# perf script flamegraph -a -F 99 sleep 60
```

This command samples and records performance data over the entire system for 60 seconds, as stipulated by use of the **sleep** command, and then constructs the visualization which will be stored in the current active directory as **flamegraph.html**. The command samples call-graph data by default and takes the same arguments as the **perf** tool, in this particular case:

-a

Stipulates to record data over the entire system.

-F

To set the sampling frequency per second.

Verification steps

- For analysis, view the generated visualization:

```
# xdg-open flamegraph.html
```

This command opens the visualization in the default browser:

27.3. CREATING FLAMEGRAPHS OVER SPECIFIC PROCESSES

You can use **flamegraphs** to visualize performance data recorded over specific running processes.

Prerequisites

- **flamegraphs** are installed as described in [installing flamegraphs](#).
- The **perf** tool is installed as described in [installing perf](#).

Procedure

- Record the data and create the visualization:

```
# perf script flamegraph -a -F 99 -p ID1,ID2 sleep 60
```

This command samples and records performance data of the processes with the process ID's **ID1** and **ID2** for 60 seconds, as stipulated by use of the **sleep** command, and then constructs the visualization which will be stored in the current active directory as **flamegraph.html**. The command samples call-graph data by default and takes the same arguments as the **perf** tool, in this particular case:

-a

Stipulates to record data over the entire system.

-F

To set the sampling frequency per second.

-p

To stipulate specific process ID's to sample and record data over.

Verification steps

- For analysis, view the generated visualization:

```
# xdg-open flamegraph.html
```

This command opens the visualization in the default browser:

27.4. INTERPRETING FLAMEGRAPHS

Each box in the flamegraph represents a different function in the stack. The y-axis shows the depth of the stack with the topmost box in each stack being the function that was actually on-CPU and everything below it being ancestry. The x-axis displays the population of the sampled call-graph data.

The children of a stack in a given row are displayed based on the number of samples taken of each respective function in descending order along the x-axis; the x-axis does not represent the passing of time. The wider an individual box is, the more frequent it was on-CPU or part of an on-CPU ancestry at the time the data was being sampled.

Procedure

- To reveal the names of functions which may have not been displayed previously and further investigate the data click on a box within the flamegraph to zoom into the stack at that given location:

- To return to the default view of the flamegraph, click **Reset Zoom**.

Boxes representing user-space functions may be labeled as **Unknown** in **flamegraphs** because the binary of the function is stripped. The **debuginfo** package of the executable must be installed or, if the executable is a locally developed application, the application must be compiled with debugging information. Use the **-g** option in GCC, to display the function names or symbols in such a situation.

- Why perf displays some function names as raw functions addresses
- Enabling debugging with debugging information

CHAPTER 28. MONITORING PROCESSES FOR PERFORMANCE BOTTLENECKS USING PERF CIRCULAR BUFFERS

You can create circular buffers that take event-specific snapshots of data with the **perf** tool in order to monitor performance bottlenecks in specific processes or parts of applications running on your system. In such cases, **perf** only writes data to a **perf.data** file for later analysis if a specified event is detected.

28.1. CIRCULAR BUFFERS AND EVENT-SPECIFIC SNAPSHOTS WITH PERF

When investigating performance issues in a process or application with **perf**, it may not be affordable or appropriate to record data for hours preceding a specific event of interest occurring. In such cases, you can use **perf record** to create custom circular buffers that take snapshots after specific events.

The **--overwrite** option makes **perf record** store all data in an overwritable circular buffer. When the buffer gets full, **perf record** automatically overwrites the oldest records which, therefore, never get written to a **perf.data** file.

Using the **--overwrite** and **--switch-output-event** options together configures a circular buffer that records and dumps data continuously until it detects the **--switch-output-event** trigger event. The trigger event signals to **perf record** that something of interest to the user has occurred and to write the data in the circular buffer to a **perf.data** file. This collects specific data you are interested in while simultaneously reducing the overhead of the running **perf** process by not writing data you do not want to a **perf.data** file.

28.2. COLLECTING SPECIFIC DATA TO MONITOR FOR PERFORMANCE BOTTLENECKS USING PERF CIRCULAR BUFFERS

With the **perf** tool, you can create circular buffers that are triggered by events you specify in order to only collect data you are interested in. To create circular buffers that collect event-specific data, use the **--overwrite** and **--switch-output-event** options for **perf**.

Prerequisites

- The **perf** user space tool is installed. For more information, see [Installing perf](#).
- You have placed a uprobe in the process or application you are interested in monitoring at a location of interest within the process or application:

```
# perf probe -x /path/to/executable -a function
Added new event:
probe_executable:function (on function in /path/to/executable)
```

You can now use it in all **perf** tools, such as:

```
perf record -e probe_executable:function -aR sleep 1
```

Procedure

- Create the circular buffer with the uprobe as the trigger event:

```
# perf record --overwrite -e cycles --switch-output-event probe_executable:function
./executable
[ perf record: dump data: Woken up 1 times ]
[ perf record: Dump perf.data.2021021012231959 ]
[ perf record: dump data: Woken up 1 times ]
[ perf record: Dump perf.data.2021021012232008 ]
^C[ perf record: dump data: Woken up 1 times ]
[ perf record: Dump perf.data.2021021012232082 ]
[ perf record: Captured and wrote 5.621 MB perf.data.<timestamp> ]
```

This example initiates the executable and collects cpu cycles, specified after the **-e** option, until **perf** detects the uprobe, the trigger event specified after the **--switch-output-event** option. At that point, **perf** takes a snapshot of all the data in the circular buffer and stores it in a unique **perf.data** file identified by timestamp. This example produced a total of 2 snapshots, the last **perf.data** file was forced by pressing **Ctrl+c**.

CHAPTER 29. ADDING AND REMOVING TRACEPOINTS FROM A RUNNING PERF COLLECTOR WITHOUT STOPPING OR RESTARTING PERF

By using the control pipe interface to enable and disable different tracepoints in a running **perf** collector, you can dynamically adjust what data you are collecting without having to stop or restart **perf**. This ensures you do not lose performance data that would have otherwise been recorded during the stopping or restarting process.

29.1. ADDING TRACEPOINTS TO A RUNNING PERF COLLECTOR WITHOUT STOPPING OR RESTARTING PERF

Add tracepoints to a running **perf** collector using the control pipe interface to adjust the data you are recording without having to stop **perf** and losing performance data.

Prerequisites

- The **perf** user space tool is installed. For more information, see [Installing perf](#).

Procedure

1. Configure the control pipe interface:

```
# mkfifo control ack perf.pipe
```

2. Run **perf record** with the control file setup and events you are interested in enabling:

```
# perf record --control=fifo:control,ack -D -1 --no-buffering -e 'sched:*' -o - > perf.pipe
```

In this example, declaring '**sched:***' after the **-e** option starts **perf record** with scheduler events.

3. In a second terminal, start the read side of the control pipe:

```
# cat perf.pipe | perf --no-pager script -i -
```

Starting the read side of the control pipe triggers the following message in the first terminal:

```
Events disabled
```

4. In a third terminal, enable a tracepoint using the control file:

```
# echo 'enable sched:sched_process_fork' > control
```

This command triggers **perf** to scan the current event list in the control file for the declared event. If the event is present, the tracepoint is enabled and the following message appears in the first terminal:

```
event sched:sched_process_fork enabled
```

Once the tracepoint is enabled, the second terminal displays the output from **perf** detecting the tracepoint:

```
bash 33349 [034] 149587.674295: sched:sched_process_fork: comm=bash pid=33349
child_comm=bash child_pid=34056
```

29.2. REMOVING TRACEPOINTS FROM A RUNNING PERF COLLECTOR WITHOUT STOPPING OR RESTARTING PERF

Remove tracepoints from a running **perf** collector using the control pipe interface to reduce the scope of data you are collecting without having to stop **perf** and losing performance data.

Prerequisites

- The **perf** user space tool is installed. For more information, see [Installing perf](#).
- You have added tracepoints to a running **perf** collector via the control pipe interface. For more information, see [Adding tracepoints to a running perf collector without stopping or restarting perf](#).

Procedure

- Remove the tracepoint:

```
# echo 'disable sched:sched_process_fork' > control
```

NOTE

This example assumes you have previously loaded scheduler events into the control file and enabled the tracepoint **sched:sched_process_fork**.

This command triggers **perf** to scan the current event list in the control file for the declared event. If the event is present, the tracepoint is disabled and the following message appears in the terminal used to configure the control pipe:

```
event sched:sched_process_fork disabled
```

CHAPTER 30. PROFILING MEMORY ALLOCATION WITH NUMASTAT

With the **numastat** tool, you can display statistics over memory allocations in a system.

The **numastat** tool displays data for each NUMA node separately. You can use this information to investigate memory performance of your system or the effectiveness of different memory policies on your system.

30.1. DEFAULT NUMASTAT STATISTICS

By default, the **numastat** tool displays statistics over these categories of data for each NUMA node:

numa_hit

The number of pages that were successfully allocated to this node.

numa_miss

The number of pages that were allocated on this node because of low memory on the intended node. Each **numa_miss** event has a corresponding **numa_foreign** event on another node.

numa_foreign

The number of pages initially intended for this node that were allocated to another node instead. Each **numa_foreign** event has a corresponding **numa_miss** event on another node.

interleave_hit

The number of interleave policy pages successfully allocated to this node.

local_node

The number of pages successfully allocated on this node by a process on this node.

other_node

The number of pages allocated on this node by a process on another node.

NOTE

High **numa_hit** values and low **numa_miss** values (relative to each other) indicate optimal performance.

30.2. VIEWING MEMORY ALLOCATION WITH NUMASTAT

You can view the memory allocation of the system by using the **numastat** tool.

Prerequisites

- Install the **numactl** package:

```
# yum install numactl
```

Procedure

- View the memory allocation of your system:

```
$ numastat
node0    node1
```

numa_hit	76557759	92126519
numa_miss	30772308	30827638
numa_foreign	30827638	30772308
interleave_hit	106507	103832
local_node	76502227	92086995
other_node	30827840	30867162

Additional resources

- **numastat(8)** man page

CHAPTER 31. CONFIGURING AN OPERATING SYSTEM TO OPTIMIZE CPU UTILIZATION

This section describes how to configure the operating system to optimize CPU utilization across their workloads.

31.1. TOOLS FOR MONITORING AND DIAGNOSING PROCESSOR ISSUES

The following are the tools available in Red Hat Enterprise Linux 8 to monitor and diagnose processor-related performance issues:

- **turbostat** tool prints counter results at specified intervals to help administrators identify unexpected behavior in servers, such as excessive power usage, failure to enter deep sleep states, or system management interrupts (SMIs) being created unnecessarily.
- **numactl** utility provides a number of options to manage processor and memory affinity. The **numactl** package includes the **libnuma** library which offers a simple programming interface to the NUMA policy supported by the kernel, and can be used for more fine-grained tuning than the **numactl** application.
- **numastat** tool displays per-NUMA node memory statistics for the operating system and its processes, and shows administrators whether the process memory is spread throughout a system or is centralized on specific nodes. This tool is provided by the **numactl** package.
- **numad** is an automatic NUMA affinity management daemon. It monitors NUMA topology and resource usage within a system in order to dynamically improve NUMA resource allocation and management.
- **/proc/interrupts** file displays the interrupt request (IRQ) number, the number of similar interrupt requests handled by each processor in the system, the type of interrupt sent, and a comma-separated list of devices that respond to the listed interrupt request.
- **pqos** utility is available in the **intel-cmt-cat** package. It monitors CPU cache and memory bandwidth on recent Intel processors. It monitors:
 - The instructions per cycle (IPC).
 - The count of last level cache MISSES.
 - The size in kilobytes that the program executing in a given CPU occupies in the LLC.
 - The bandwidth to local memory (MBL).
 - The bandwidth to remote memory (MBR).
- **x86_energy_perf_policy** tool allows administrators to define the relative importance of performance and energy efficiency. This information can then be used to influence processors that support this feature when they select options that trade off between performance and energy efficiency.
- **taskset** tool is provided by the **util-linux** package. It allows administrators to retrieve and set the processor affinity of a running process, or launch a process with a specified processor affinity.

Additional resources

- **turbostat(8)**, **numactl(8)**, **numastat(8)**, **numa(7)**, **numad(8)**, **pqos(8)**, **x86_energy_perf_policy(8)**, and **taskset(1)** man pages

31.2. TYPES OF SYSTEM TOPOLOGY

In modern computing, the idea of a CPU is a misleading one, as most modern systems have multiple processors. The topology of the system is the way these processors are connected to each other and to other system resources. This can affect system and application performance, and the tuning considerations for a system.

The following are the two primary types of topology used in modern computing:

Symmetric Multi-Processor (SMP) topology

SMP topology allows all processors to access memory in the same amount of time. However, because shared and equal memory access inherently forces serialized memory accesses from all the CPUs, SMP system scaling constraints are now generally viewed as unacceptable. For this reason, practically all modern server systems are NUMA machines.

Non-Uniform Memory Access (NUMA) topology

NUMA topology was developed more recently than SMP topology. In a NUMA system, multiple processors are physically grouped on a socket. Each socket has a dedicated area of memory and processors that have local access to that memory, these are referred to collectively as a node. Processors on the same node have high speed access to that node's memory bank, and slower access to memory banks not on their node.

Therefore, there is a performance penalty when accessing non-local memory. Thus, performance sensitive applications on a system with NUMA topology should access memory that is on the same node as the processor executing the application, and should avoid accessing remote memory wherever possible.

Multi-threaded applications that are sensitive to performance may benefit from being configured to execute on a specific NUMA node rather than a specific processor. Whether this is suitable depends on your system and the requirements of your application. If multiple application threads access the same cached data, then configuring those threads to execute on the same processor may be suitable. However, if multiple threads that access and cache different data execute on the same processor, each thread may evict cached data accessed by a previous thread. This means that each thread 'misses' the cache and wastes execution time fetching data from memory and replacing it in the cache. Use the **perf** tool to check for an excessive number of cache misses.

31.2.1. Displaying system topologies

There are a number of commands that help understand the topology of a system. This procedure describes how to determine the system topology.

Procedure

- To display an overview of your system topology:

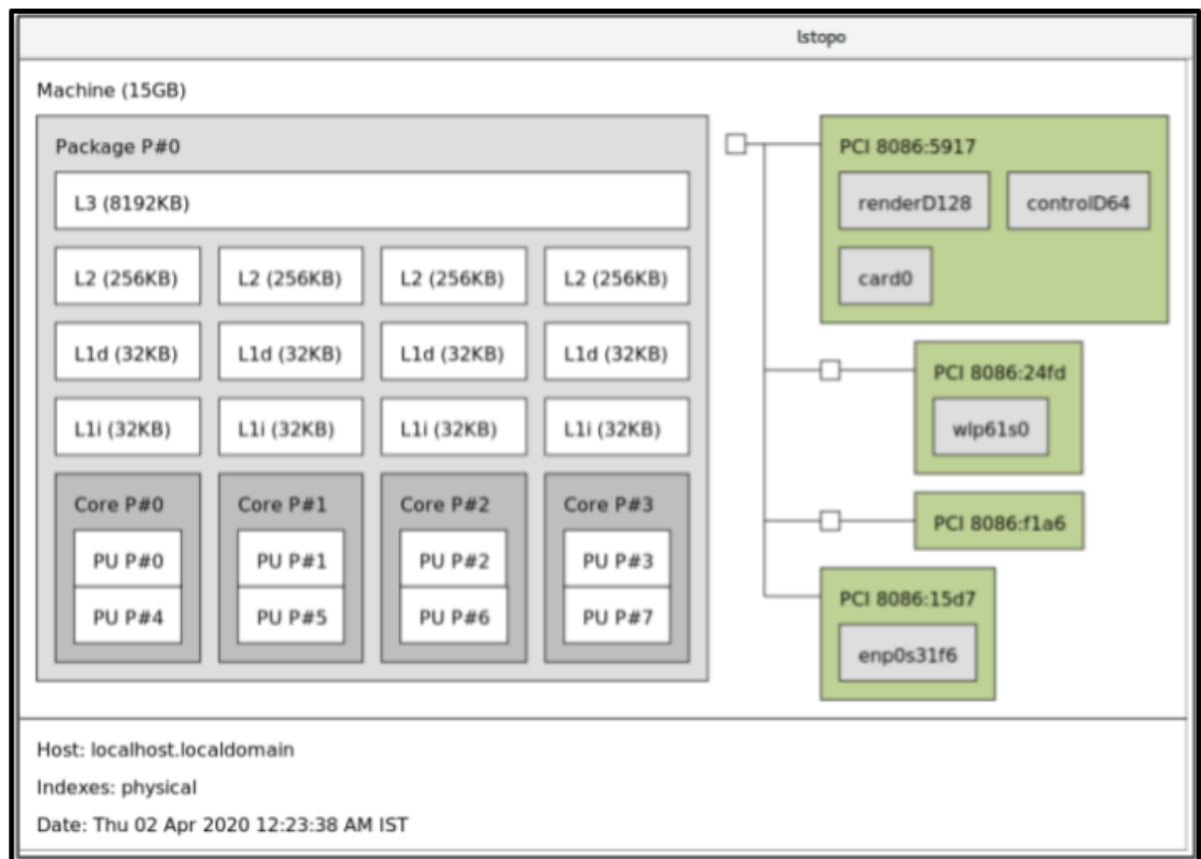

```
$ numactl --hardware
available: 4 nodes (0-3)
node 0 cpus: 0 4 8 12 16 20 24 28 32 36
node 0 size: 65415 MB
node 0 free: 43971 MB
[...]
```

- To gather the information about the CPU architecture, such as the number of CPUs, threads, cores, sockets, and NUMA nodes:

```
$ lscpu
Architecture:          x86_64
CPU op-mode(s):        32-bit, 64-bit
Byte Order:             Little Endian
CPU(s):                 40
On-line CPU(s) list:   0-39
Thread(s) per core:     1
Core(s) per socket:     10
Socket(s):              4
NUMA node(s):           4
Vendor ID:              GenuineIntel
CPU family:              6
Model:                  47
Model name:              Intel(R) Xeon(R) CPU E7- 4870  @ 2.40GHz
Stepping:                2
CPU MHz:                 2394.204
BogoMIPS:                4787.85
Virtualization:         VT-x
L1d cache:               32K
L1i cache:               32K
L2 cache:                256K
L3 cache:                30720K
NUMA node0 CPU(s):      0,4,8,12,16,20,24,28,32,36
NUMA node1 CPU(s):      2,6,10,14,18,22,26,30,34,38
NUMA node2 CPU(s):      1,5,9,13,17,21,25,29,33,37
NUMA node3 CPU(s):      3,7,11,15,19,23,27,31,35,39
```

- To view a graphical representation of your system:

```
# yum install hwloc-gui
# lstopo
```

Figure 31.1. The **Istopo** output

- To view the detailed textual output:

```
# yum install hwloc
# Istopo-no-graphics
Machine (15GB)
Package L#0 + L3 L#0 (8192KB)
  L2 L#0 (256KB) + L1d L#0 (32KB) + L1i L#0 (32KB) + Core L#0

31.3. CONFIGURING KERNEL TICK TIME

By default, Red Hat Enterprise Linux 8 uses a tickless kernel, which does not interrupt idle CPUs in order to reduce power usage and allow new processors to take advantage of deep sleep states.

Red Hat Enterprise Linux 8 also offers a dynamic tickless option, which is useful for latency-sensitive workloads, such as high performance computing or realtime computing. By default, the dynamic tickless option is disabled. Red Hat recommends using the **cpu-partitioning TuneD** profile to enable the dynamic tickless option for cores specified as **isolated_cores**.

This procedure describes how to manually persistently enable dynamic tickless behavior.

Procedure

1. To enable dynamic tickless behavior in certain cores, specify those cores on the kernel command line with the **nohz_full** parameter. On a 16 core system, append this parameter on the **GRUB_CMDLINE_LINUX** option in the **/etc/default/grub** file:

```
nohz_full=1-15
```

This enables dynamic tickless behavior on cores **1** through **15**, moving all timekeeping to the only unspecified core (core **0**).

2. To persistently enable the dynamic tickless behavior, regenerate the GRUB2 configuration using the edited default file. On systems with BIOS firmware, execute the following command:

```
# grub2-mkconfig -o /etc/grub2.cfg
```

On systems with UEFI firmware, execute the following command:

```
# grub2-mkconfig -o /etc/grub2-efi.cfg
```

3. When the system boots, manually move the **rcu** threads to the non-latency-sensitive core, in this case core **0**:

```
# for i in `pgrep rcu[^c]`; do taskset -pc 0 $i ; done
```

4. Optional: Use the **isolcpus** parameter on the kernel command line to isolate certain cores from user-space tasks.
5. Optional: Set the CPU affinity for the kernel's **write-back bdi-flush** threads to the housekeeping core:

```
echo 1 > /sys/bus/workqueue/devices/writeback/cpumask
```

Verification steps

- Once the system is rebooted, verify if **dynticks** are enabled:

```
# journalctl -xe | grep dynticks
Mar 15 18:34:54 rhel-server kernel: NO_HZ: Full dynticks CPUs: 1-15.
```

- Verify that the dynamic tickless configuration is working correctly:

```
# perf stat -C 1 -e irq_vectors:local_timer_entry taskset -c 1 sleep 3
```

This command measures ticks on CPU 1 while telling CPU 1 to sleep for 3 seconds.

- The default kernel timer configuration shows around 3100 ticks on a regular CPU:

```
# perf stat -C 0 -e irq_vectors:local_timer_entry taskset -c 0 sleep 3

Performance counter stats for 'CPU(s) 0':

      3,107      irq_vectors:local_timer_entry

      3.001342790 seconds time elapsed
```

- With the dynamic tickless kernel configured, you should see around 4 ticks instead:

```
# perf stat -C 1 -e irq_vectors:local_timer_entry taskset -c 1 sleep 3

Performance counter stats for 'CPU(s) 1':

         4      irq_vectors:local_timer_entry

      3.001544078 seconds time elapsed
```

31.4. OVERVIEW OF AN INTERRUPT REQUEST

An interrupt request or IRQ is a signal for immediate attention sent from a piece of hardware to a processor. Each device in a system is assigned one or more IRQ numbers which allow it to send unique interrupts. When interrupts are enabled, a processor that receives an interrupt request immediately pauses execution of the current application thread in order to address the interrupt request.

Because interrupt halts normal operation, high interrupt rates can severely degrade system performance. It is possible to reduce the amount of time taken by interrupts by configuring interrupt affinity or by sending a number of lower priority interrupts in a batch (coalescing a number of interrupts).

Interrupt requests have an associated affinity property, **smp_affinity**, which defines the processors that handle the interrupt request. To improve application performance, assign interrupt affinity and process affinity to the same processor, or processors on the same core. This allows the specified interrupt and application threads to share cache lines.

On systems that support interrupt steering, modifying the **smp_affinity** property of an interrupt request sets up the hardware so that the decision to service an interrupt with a particular processor is made at the hardware level with no intervention from the kernel.

31.4.1. Balancing interrupts manually

If your BIOS exports its NUMA topology, the **irqbalance** service can automatically serve interrupt requests on the node that is local to the hardware requesting service.

Procedure

1. Check which devices correspond to the interrupt requests that you want to configure.
2. Find the hardware specification for your platform. Check if the chipset on your system supports distributing interrupts.
 - a. If it does, you can configure interrupt delivery as described in the following steps. Additionally, check which algorithm your chipset uses to balance interrupts. Some BIOSes have options to configure interrupt delivery.
 - b. If it does not, your chipset always routes all interrupts to a single, static CPU. You cannot configure which CPU is used.
3. Check which Advanced Programmable Interrupt Controller (APIC) mode is in use on your system:

```
$ journalctl --dmesg | grep APIC
```

Here,

- If your system uses a mode other than **flat**, you can see a line similar to **Setting APIC routing to physical flat**.
- If you can see no such message, your system uses **flat** mode.
If your system uses **x2apic** mode, you can disable it by adding the **nox2apic** option to the kernel command line in the **bootloader** configuration.

Only non-physical flat mode (**flat**) supports distributing interrupts to multiple CPUs. This mode is available only for systems that have up to **8** CPUs.

4. Calculate the **smp_affinity mask**. For more information on how to calculate the **smp_affinity mask**, see [Setting the smp_affinity mask](#).

Additional resources

- **journalctl(1)** and **taskset(1)** man pages

31.4.2. Setting the smp_affinity mask

The **smp_affinity** value is stored as a hexadecimal bit mask representing all processors in the system. Each bit configures a different CPU. The least significant bit is CPU 0.

The default value of the mask is **f**, which means that an interrupt request can be handled on any processor in the system. Setting this value to 1 means that only processor 0 can handle the interrupt.

Procedure

1. In binary, use the value 1 for CPUs that handle the interrupts. For example, to set CPU 0 and CPU 7 to handle interrupts, use **0000000010000001** as the binary code:

Table 31.1. Binary Bits for CPUs

CPU	1 5	1 4	1 3	1 2	11	1 0	9	8	7	6	5	4	3	2	1	0
Binary	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	1

- Convert the binary code to hexadecimal:

For example, to convert the binary code using Python:

```
>>> hex(int('0000000010000001', 2))
'0x81'
```

On systems with more than 32 processors, you must delimit the **smp_affinity** values for discrete 32 bit groups. For example, if you want only the first 32 processors of a 64 processor system to service an interrupt request, use **0xffffffff,00000000**.

- The interrupt affinity value for a particular interrupt request is stored in the associated **/proc/irq/irq_number/smp_affinity** file. Set the **smp_affinity** mask in this file:

```
# echo mask > /proc/irq/irq_number/smp_affinity
```

Additional resources

- journalctl(1)**, **irqbalance(1)**, and **taskset(1)** man pages

CHAPTER 32. TUNING SCHEDULING POLICY

In Red Hat Enterprise Linux, the smallest unit of process execution is called a thread. The system scheduler determines which processor runs a thread, and for how long the thread runs. However, because the scheduler's primary concern is to keep the system busy, it may not schedule threads optimally for application performance.

For example, say an application on a NUMA system is running on Node A when a processor on Node B becomes available. To keep the processor on Node B busy, the scheduler moves one of the application's threads to Node B. However, the application thread still requires access to memory on Node A. But, this memory will take longer to access because the thread is now running on Node B and Node A memory is no longer local to the thread. Thus, it may take longer for the thread to finish running on Node B than it would have taken to wait for a processor on Node A to become available, and then to execute the thread on the original node with local memory access.

32.1. CATEGORIES OF SCHEDULING POLICIES

Performance sensitive applications often benefit from the designer or administrator determining where threads are run. The Linux scheduler implements a number of scheduling policies which determine where and for how long a thread runs.

The following are the two major categories of scheduling policies:

Normal policies

Normal threads are used for tasks of normal priority.

Realtime policies

Realtime policies are used for time-sensitive tasks that must complete without interruptions. Realtime threads are not subject to time slicing. This means the thread runs until they block, exit, voluntarily yield, or are preempted by a higher priority thread.

The lowest priority realtime thread is scheduled before any thread with a normal policy. For more information, see [Static priority scheduling with SCHED_FIFO](#) and [Round robin priority scheduling with SCHED_RR](#).

Additional resources

- `sched(7)`, `sched_setaffinity(2)`, `sched_getaffinity(2)`, `sched_setscheduler(2)`, and `sched_getscheduler(2)` man pages

32.2. STATIC PRIORITY SCHEDULING WITH SCHED_FIFO

The **SCHED_FIFO**, also called static priority scheduling, is a realtime policy that defines a fixed priority for each thread. This policy allows administrators to improve event response time and reduce latency. It is recommended to not execute this policy for an extended period of time for time sensitive tasks.

When **SCHED_FIFO** is in use, the scheduler scans the list of all the **SCHED_FIFO** threads in order of priority and schedules the highest priority thread that is ready to run. The priority level of a **SCHED_FIFO** thread can be any integer from **1** to **99**, where **99** is treated as the highest priority. Red Hat recommends starting with a lower number and increasing priority only when you identify latency issues.

WARNING

Because realtime threads are not subject to time slicing, Red Hat does not recommend setting a priority as 99. This keeps your process at the same priority level as migration and watchdog threads; if your thread goes into a computational loop and these threads are blocked, they will not be able to run. Systems with a single processor will eventually hang in this situation.

Administrators can limit **SCHED_FIFO** bandwidth to prevent realtime application programmers from initiating realtime tasks that monopolize the processor.

The following are some of the parameters used in this policy:

/proc/sys/kernel/sched_rt_period_us

This parameter defines the time period, in microseconds, that is considered to be one hundred percent of the processor bandwidth. The default value is **1000000 µs**, or **1 second**.

/proc/sys/kernel/sched_rt_runtime_us

This parameter defines the time period, in microseconds, that is devoted to running real-time threads. The default value is **950000 µs**, or **0.95 seconds**.

32.3. ROUND ROBIN PRIORITY SCHEDULING WITH SCHED_RR

The **SCHED_RR** is a round-robin variant of the **SCHED_FIFO**. This policy is useful when multiple threads need to run at the same priority level.

Like **SCHED_FIFO**, **SCHED_RR** is a realtime policy that defines a fixed priority for each thread. The scheduler scans the list of all **SCHED_RR** threads in order of priority and schedules the highest priority thread that is ready to run. However, unlike **SCHED_FIFO**, threads that have the same priority are scheduled in a round-robin style within a certain time slice.

You can set the value of this time slice in milliseconds with the **sched_rr_timeslice_ms** kernel parameter in the **/proc/sys/kernel/sched_rr_timeslice_ms** file. The lowest value is **1 millisecond**.

32.4. NORMAL SCHEDULING WITH SCHED_OTHER

The **SCHED_OTHER** is the default scheduling policy in Red Hat Enterprise Linux 8. This policy uses the Completely Fair Scheduler (CFS) to allow fair processor access to all threads scheduled with this policy. This policy is most useful when there are a large number of threads or when data throughput is a priority, as it allows more efficient scheduling of threads over time.

When this policy is in use, the scheduler creates a dynamic priority list based partly on the niceness value of each process thread. Administrators can change the niceness value of a process, but cannot change the scheduler's dynamic priority list directly.

32.5. SETTING SCHEDULER POLICIES

Check and adjust scheduler policies and priorities by using the **chrt** command line tool. It can start new processes with the desired properties, or change the properties of a running process. It can also be used for setting the policy at runtime.

Procedure

1. View the process ID (PID) of the active processes:

```
# ps
```

Use the **--pid** or **-p** option with the **ps** command to view the details of the particular PID.

2. Check the scheduling policy, PID, and priority of a particular process:

```
# chrt -p 468
pid 468's current scheduling policy: SCHED_FIFO
pid 468's current scheduling priority: 85

# chrt -p 476
pid 476's current scheduling policy: SCHED_OTHER
pid 476's current scheduling priority: 0
```

Here, *468* and *476* are PID of a process.

3. Set the scheduling policy of a process:

- a. For example, to set the process with PID *1000* to *SCHED_FIFO*, with a priority of *50*:

```
# chrt -f -p 50 1000
```

- b. For example, to set the process with PID *1000* to *SCHED_OTHER*, with a priority of *0*:

```
# chrt -o -p 0 1000
```

- c. For example, to set the process with PID *1000* to *SCHED_RR*, with a priority of *10*:

```
# chrt -r -p 10 1000
```

- d. To start a new application with a particular policy and priority, specify the name of the application:

```
# chrt -f 36 /bin/my-app
```

Additional resources

- **chrt(1)** man page
- [Policy Options for the chrt command](#)
- [Changing the priority of services during the boot process](#)

32.6. POLICY OPTIONS FOR THE CHRT COMMAND

Using the **chrt** command, you can view and set the scheduling policy of a process.

The following table describes the appropriate policy options, which can be used to set the scheduling policy of a process.

Table 32.1. Policy Options for the `chrt` Command

Short option	Long option	Description
-f	--fifo	Set schedule to SCHED_FIFO
-o	--other	Set schedule to SCHED_OTHER
-r	--rr	Set schedule to SCHED_RR

32.7. CHANGING THE PRIORITY OF SERVICES DURING THE BOOT PROCESS

Using the **systemd** service, it is possible to set up real-time priorities for services launched during the boot process. The *unit configuration directives* are used to change the priority of a service during the boot process.

The boot process priority change is done by using the following directives in the service section:

CPUSchedulingPolicy=

Sets the CPU scheduling policy for executed processes. It is used to set **other**, **fifo**, and **rr** policies.

CPUSchedulingPriority=

Sets the CPU scheduling priority for executed processes. The available priority range depends on the selected CPU scheduling policy. For real-time scheduling policies, an integer between **1** (lowest priority) and **99** (highest priority) can be used.

The following procedure describes how to change the priority of a service, during the boot process, using the **mcelog** service.

Prerequisites

1. Install the tuned package:

```
# yum install tuned
```

2. Enable and start the tuned service:

```
# systemctl enable --now tuned
```

Procedure

1. View the scheduling priorities of running threads:

```
# tuna --show_threads
          thread    ctxt_switches
pid SCHED_ rtpri affinity voluntary nonvoluntary  cmd
1  OTHER   0    0xff   3181      292    systemd
2  OTHER   0    0xff    254        0    kthreadd
3  OTHER   0    0xff     2         0    rcu_gp
4  OTHER   0    0xff     2         0    rcu_par_gp
```

```

6  OTHER  0    0    9      0 kworker/0:0H-kblockd
7  OTHER  0  0xff 1301    1 kworker/u16:0-events_unbound
8  OTHER  0  0xff  2      0 mm_percpu_wq
9  OTHER  0    0 266      0 ksoftirqd/0
[...]
```

2. Create a supplementary **mcelog** service configuration directory file and insert the policy name and priority in this file:

```

# cat <<-EOF > /etc/systemd/system/mcelog.system.d/priority.conf

>
[SERVICE]
CPUSchedulingPolicy=_fifo_
CPUSchedulingPriority=_20_
EOF
```

3. Reload the **systemd** scripts configuration:

```
# systemctl daemon-reload
```

4. Restart the **mcelog** service:

```
# systemctl restart mcelog
```

Verification steps

- Display the **mcelog** priority set by **systemd** issue:

```

# tuna -t mcelog -P
thread  ctxt_switches
pid SCHED_ rtpri affinity voluntary nonvoluntary  cmd
826  FIFO   20 0,1,2,3   13      0      mcelog
```

Additional resources

- **systemd(1)** and **tuna(8)** man pages
- [Description of the priority range](#)

32.8. PRIORITY MAP

Priorities are defined in groups, with some groups dedicated to certain kernel functions. For real-time scheduling policies, an integer between **1** (lowest priority) and **99** (highest priority) can be used.

The following table describes the priority range, which can be used while setting the scheduling policy of a process.

Table 32.2. Description of the priority range

Priority	Threads	Description
1	Low priority kernel threads	This priority is usually reserved for the tasks that need to be just above SCHED_OTHER .
2 - 49	Available for use	The range used for typical application priorities.
50	Default hard-IRQ value	
51 - 98	High priority threads	Use this range for threads that execute periodically and must have quick response times. Do not use this range for CPU-bound threads as you will starve interrupts.
99	Watchdogs and migration	System threads that must run at the highest priority.

32.9. TUNED CPU-PARTITIONING PROFILE

For tuning Red Hat Enterprise Linux 8 for latency-sensitive workloads, Red Hat recommends to use the **cpu-partitioning** Tuned profile.

Prior to Red Hat Enterprise Linux 8, the low-latency Red Hat documentation described the numerous low-level steps needed to achieve low-latency tuning. In Red Hat Enterprise Linux 8, you can perform low-latency tuning more efficiently by using the **cpu-partitioning** Tuned profile. This profile is easily customizable according to the requirements for individual low-latency applications.

The following figure is an example to demonstrate how to use the **cpu-partitioning** profile. This example uses the `cpu` and `node` layout.

Figure 32.1. Figure `cpu-partitioning`

You can configure the `cpu-partitioning` profile in the `/etc/tuned/cpu-partitioning-variables.conf` file using the following configuration options:

Isolated cpus with load balancing

In the `cpu-partitioning` figure, the blocks numbered from 4 to 23, are the default isolated cpus. The kernel scheduler's process load balancing is enabled on these cpus. It is designed for low-latency processes with multiple threads that need the kernel scheduler load balancing.

You can configure the `cpu-partitioning` profile in the `/etc/tuned/cpu-partitioning-variables.conf` file using the **`isolated_cores=cpu-list`** option, which lists CPUs to isolate that will use the kernel scheduler load balancing.

The list of isolated CPUs is comma-separated or you can specify a range using a dash, such as **`3-5`**. This option is mandatory. Any CPU missing from this list is automatically considered a housekeeping CPU.

Isolated cpus without load balancing

In the `cpu-partitioning` figure, the blocks numbered 2 and 3, are the isolated cpus that do not provide any additional kernel scheduler process load balancing.

You can configure the `cpu-partitioning` profile in the `/etc/tuned/cpu-partitioning-variables.conf` file using the **`no_balance_cores=cpu-list`** option, which lists CPUs to isolate that will not use the kernel scheduler load balancing.

Specifying the **`no_balance_cores`** option is optional, however any cpus in this list must be a subset of the cpus listed in the **`isolated_cores`** list.

Application threads using these cpus need to be pinned individually to each cpu.

Housekeeping cpus

Any cpu not isolated in the `cpu-partitioning-variables.conf` file is automatically considered a housekeeping cpu. On the housekeeping cpu, all services, daemons, user processes, movable kernel threads, interrupt handlers, and kernel timers are permitted to execute.

Additional resources

- **`tuned-profiles-cpu-partitioning(7)`** man page

32.10. USING THE TUNED CPU-PARTITIONING PROFILE FOR LOW-LATENCY TUNING

This procedure describes how to tune a system for low-latency using the TuneD's **`cpu-partitioning`** profile. It uses the example of a low-latency application that can use **`cpu-partitioning`** and the CPU layout as mentioned in the [cpu-partitioning](#) figure.

The application in this case uses:

- One dedicated reader thread that reads data from the network will be pinned to CPU 2.
- A large number of threads that process this network data will be pinned to CPUs 4-23.
- A dedicated writer thread that writes the processed data to the network will be pinned to CPU 3.

Prerequisites

- You have installed the **`cpu-partitioning`** TuneD profile by using the **`yum install tuned-profiles-cpu-partitioning`** command as root.

Procedure

1. Edit **/etc/tuned/cpu-partitioning-variables.conf** file and add the following information:

```
# Isolated CPUs with the kernel's scheduler load balancing:
isolated_cores=2-23
# Isolated CPUs without the kernel's scheduler load balancing:
no_balance_cores=2,3
```

2. Set the **cpu-partitioning** TuneD profile:

```
# tuned-adm profile cpu-partitioning
```

3. Reboot

After rebooting, the system is tuned for low-latency, according to the isolation in the **cpu-partitioning** figure. The application can use **taskset** to pin the reader and writer threads to cpus 2 and 3, and the remaining application threads on cpus 4-23.

Additional resources

- **tuned-profiles-cpu-partitioning(7)** man page

32.11. CUSTOMIZING THE CPU-PARTITIONING TUNED PROFILE

You can extend the TuneD profile to make additional tuning changes.

For example, the **cpu-partitioning** profile sets the cpus to use **cstate=1**. In order to use the **cpu-partitioning** profile but to additionally change the CPU cstate from **cstate1** to **cstate0**, the following procedure describes a new TuneD profile named *my_profile*, which inherits the **cpu-partitioning** profile and then sets C state-0.

Procedure

1. Create the **/etc/tuned/my_profile** directory:

```
# mkdir /etc/tuned/my_profile
```

2. Create a **tuned.conf** file in this directory, and add the following content:

```
# vi /etc/tuned/my_profile/tuned.conf
[main]
summary=Customized tuning on top of cpu-partitioning
include=cpu-partitioning
[cpu]
force_latency=cstate.id:0|1
```

3. Use the new profile:

```
# tuned-adm profile my_profile
```

**NOTE**

In the shared example, a reboot is not required. However, if the changes in the *my_profile* profile require a reboot to take effect, then reboot your machine.

Additional resources

- **tuned-profiles-cpu-partitioning(7)** man page

CHAPTER 33. FACTORS AFFECTING I/O AND FILE SYSTEM PERFORMANCE

The appropriate settings for storage and file system performance are highly dependent on the storage purpose.

I/O and file system performance can be affected by any of the following factors:

- Data write or read patterns
- Sequential or random
- Buffered or Direct IO
- Data alignment with underlying geometry
- Block size
- File system size
- Journal size and location
- Recording access times
- Ensuring data reliability
- Pre-fetching data
- Pre-allocating disk space
- File fragmentation
- Resource contention

33.1. TOOLS FOR MONITORING AND DIAGNOSING I/O AND FILE SYSTEM ISSUES

The following tools are available in Red Hat Enterprise Linux 8 for monitoring system performance and diagnosing performance problems related to I/O, file systems, and their configuration:

- **vmstat** tool reports on processes, memory, paging, block I/O, interrupts, and CPU activity across the entire system. It can help administrators determine whether the I/O subsystem is responsible for any performance issues. If analysis with **vmstat** shows that the I/O subsystem is responsible for reduced performance, administrators can use the **iostat** tool to determine the responsible I/O device.
- **iostat** reports on I/O device load in your system. It is provided by the **sysstat** package.
- **blktrace** provides detailed information about how time is spent in the I/O subsystem. The companion utility **blkparse** reads the raw output from **blktrace** and produces a human readable summary of input and output operations recorded by **blktrace**.
- **btt** analyzes **blktrace** output and displays the amount of time that data spends in each area of the I/O stack, making it easier to spot bottlenecks in the I/O subsystem. This utility is provided as part of the **blktrace** package. Some of the important events tracked by the **blktrace** mechanism and analyzed by **btt** are:

- Queuing of the I/O event (**Q**)
- Dispatch of the I/O to the driver event (**D**)
- Completion of I/O event (**C**)
- **iowatcher** can use the **blktrace** output to graph I/O over time. It focuses on the Logical Block Address (LBA) of disk I/O, throughput in megabytes per second, the number of seeks per second, and I/O operations per second. This can help to identify when you are hitting the operations-per-second limit of a device.
- BPF Compiler Collection (BCC) is a library, which facilitates the creation of the extended Berkeley Packet Filter (**eBPF**) programs. The **eBPF** programs are triggered on events, such as disk I/O, TCP connections, and process creations. The BCC tools are installed in the **/usr/share/bcc/tools/** directory. The following **bcc-tools** helps to analyze performance:
 - **biolatency** summarizes the latency in block device I/O (disk I/O) in histogram. This allows the distribution to be studied, including two modes for device cache hits and for cache misses, and latency outliers.
 - **biosnoop** is a basic block I/O tracing tool for displaying each I/O event along with the issuing process ID, and the I/O latency. Using this tool, you can investigate disk I/O performance issues.
 - **biotop** is used for block i/o operations in the kernel.
 - **filelife** tool traces the **stat()** syscalls.
 - **fileslower** traces slow synchronous file reads and writes.
 - **filetop** displays file reads and writes by process.
 - **ext4slower**, **nfsslower**, and **xfsslower** are tools that show file system operations slower than a certain threshold, which defaults to **10ms**.
For more information, see the [Analyzing system performance with BPF Compiler Collection](#) .
- **bpftool** is a tracing language for **eBPF** used for analyzing performance issues. It also provides trace utilities like BCC for system observation, which is useful for investigating I/O performance issues.
- The following **SystemTap** scripts may be useful in diagnosing storage or file system performance problems:
 - **disktop.stp**: Checks the status of reading or writing disk every 5 seconds and outputs the top ten entries during that period.
 - **iotime.stp**: Prints the amount of time spent on read and write operations, and the number of bytes read and written.
 - **traceio.stp**: Prints the top ten executable based on cumulative I/O traffic observed, every second.
 - **traceio2.stp**: Prints the executable name and process identifier as reads and writes to the specified device occur.
 - **Inodewatch.stp**: Prints the executable name and process identifier each time a read or write occurs to the specified inode on the specified major or minor device.

- **inodewatch2.stp**: Prints the executable name, process identifier, and attributes each time the attributes are changed on the specified inode on the specified major or minor device.

Additional resources

- **vmstat(8)**, **iostat(1)**, **blktrace(8)**, **blkparse(1)**, **btt(1)**, **bpfftrace**, and **iowatcher(1)** man pages
- [Analyzing system performance with BPF Compiler Collection](#)

33.2. AVAILABLE TUNING OPTIONS FOR FORMATTING A FILE SYSTEM

Some file system configuration decisions cannot be changed after the device is formatted.

The following are the options available before formatting a storage device:

Size

Create an appropriately-sized file system for your workload. Smaller file systems require less time and memory for file system checks. However, if a file system is too small, its performance suffers from high fragmentation.

Block size

The block is the unit of work for the file system. The block size determines how much data can be stored in a single block, and therefore the smallest amount of data that is written or read at one time. The default block size is appropriate for most use cases. However, your file system performs better and stores data more efficiently if the block size or the size of multiple blocks is the same as or slightly larger than the amount of data that is typically read or written at one time. A small file still uses an entire block. Files can be spread across multiple blocks, but this can create additional runtime overhead.

Additionally, some file systems are limited to a certain number of blocks, which in turn limits the maximum size of the file system. Block size is specified as part of the file system options when formatting a device with the **mkfs** command. The parameter that specifies the block size varies with the file system.

Geometry

File system geometry is concerned with the distribution of data across a file system. If your system uses striped storage, like RAID, you can improve performance by aligning data and metadata with the underlying storage geometry when you format the device.

Many devices export recommended geometry, which is then set automatically when the devices are formatted with a particular file system. If your device does not export these recommendations, or you want to change the recommended settings, you must specify geometry manually when you format the device with the **mkfs** command.

The parameters that specify file system geometry vary with the file system.

External journals

Journaling file systems document the changes that will be made during a write operation in a journal file prior to the operation being executed. This reduces the likelihood that a storage device will become corrupted in the event of a system crash or power failure, and speeds up the recovery process.

**NOTE**

Red Hat does not recommend using the external journals option.

Metadata-intensive workloads involve very frequent updates to the journal. A larger journal uses more memory, but reduces the frequency of write operations. Additionally, you can improve the seek time of a device with a metadata-intensive workload by placing its journal on dedicated storage that is as fast as, or faster than, the primary storage.

**WARNING**

Ensure that external journals are reliable. Losing an external journal device causes file system corruption. External journals must be created at format time, with journal devices being specified at mount time.

Additional resources

- **mkfs(8)** and **mount(8)** man pages
- [Overview of available file systems](#)

33.3. AVAILABLE TUNING OPTIONS FOR MOUNTING A FILE SYSTEM

The following are the options available to most file systems and can be specified as the device is mounted:

Access Time

Every time a file is read, its metadata is updated with the time at which access occurred (**atime**). This involves additional write I/O. The **relatime** is the default **atime** setting for most file systems. However, if updating this metadata is time consuming, and if accurate access time data is not required, you can mount the file system with the **noatime** mount option. This disables updates to metadata when a file is read. It also enables **nodiratime** behavior, which disables updates to metadata when a directory is read.

**NOTE**

Disabling **atime** updates by using the **noatime mount** option can break applications that rely on them, for example, backup programs.

Read-ahead

Read-ahead behavior speeds up file access by pre-fetching data that is likely to be needed soon and loading it into the page cache, where it can be retrieved more quickly than if it were on disk. The higher the read-ahead value, the further ahead the system pre-fetches data.

Red Hat Enterprise Linux attempts to set an appropriate read-ahead value based on what it detects about your file system. However, accurate detection is not always possible. For example, if a storage array presents itself to the system as a single LUN, the system detects the single LUN, and does not set the appropriate read-ahead value for an array.

Workloads that involve heavy streaming of sequential I/O often benefit from high read-ahead values. The storage-related tuned profiles provided with Red Hat Enterprise Linux raise the read-ahead value, as does using LVM striping, but these adjustments are not always sufficient for all workloads.

Additional resources

- **mount(8)**, **xfs(5)**, and **ext4(5)** man pages

33.4. TYPES OF DISCARDING UNUSED BLOCKS

Regularly discarding blocks that are not in use by the file system is a recommended practice for both solid-state disks and thinly-provisioned storage.

The following are the two methods of discarding unused blocks:

Batch discard

This type of discard is part of the **fstrim** command. It discards all unused blocks in a file system that match criteria specified by the administrator. Red Hat Enterprise Linux 8 supports batch discard on XFS and ext4 formatted devices that support physical discard operations.

Online discard

This type of discard operation is configured at mount time with the discard option, and runs in real time without user intervention. However, it only discards blocks that are transitioning from used to free. Red Hat Enterprise Linux 8 supports online discard on XFS and ext4 formatted devices.

Red Hat recommends batch discard, except where online discard is required to maintain performance, or where batch discard is not feasible for the system's workload.

Pre-allocation marks disk space as being allocated to a file without writing any data into that space. This can be useful in limiting data fragmentation and poor read performance. Red Hat Enterprise Linux 8 supports pre-allocating space on XFS, ext4, and GFS2 file systems. Applications can also benefit from pre-allocating space by using the **fallocate(2) glibc** call.

Additional resources

- **mount(8)** and **fallocate(2)** man pages

33.5. SOLID-STATE DISKS TUNING CONSIDERATIONS

Solid-state disks (SSD) use NAND flash chips rather than rotating magnetic platters to store persistent data. SSD provides a constant access time for data across their full Logical Block Address range, and does not incur measurable seek costs like their rotating counterparts. They are more expensive per gigabyte of storage space and have a lesser storage density, but they also have lower latency and greater throughput than HDDs.

Performance generally degrades as the used blocks on an SSD approach the capacity of the disk. The degree of degradation varies by vendor, but all devices experience degradation in this circumstance. Enabling discard behavior can help to alleviate this degradation. For more information, see [Types of discarding unused blocks](#).

The default I/O scheduler and virtual memory options are suitable for use with SSDs. Consider the following factors when configuring settings that can affect SSD performance:

I/O Scheduler

Any I/O scheduler is expected to perform well with most SSDs. However, as with any other storage type, Red Hat recommends benchmarking to determine the optimal configuration for a given workload. When using SSDs, Red Hat advises changing the I/O scheduler only for benchmarking particular workloads. For instructions on how to switch between I/O schedulers, see the [/usr/share/doc/kernel-version/Documentation/block/switching-sched.txt](#) file.

For single queue HBA, the default I/O scheduler is **deadline**. For multiple queue HBA, the default I/O scheduler is **none**. For information on how to set the I/O scheduler, see [Setting the disk scheduler](#).

Virtual Memory

Like the I/O scheduler, virtual memory (VM) subsystem requires no special tuning. Given the fast nature of I/O on SSD, try turning down the **vm_dirty_background_ratio** and **vm_dirty_ratio** settings, as increased write-out activity does not usually have a negative impact on the latency of other operations on the disk. However, this tuning can generate more overall I/O, and is therefore not generally recommended without workload-specific testing.

Swap

An SSD can also be used as a swap device, and is likely to produce good page-out and page-in performance.

33.6. GENERIC BLOCK DEVICE TUNING PARAMETERS

The generic tuning parameters listed in this section are available in the **/sys/block/sdX/queue/** directory.

The following listed tuning parameters are separate from I/O scheduler tuning, and are applicable to all I/O schedulers:

add_random

Some I/O events contribute to the entropy pool for the **/dev/random**. This parameter can be set to **0** if the overhead of these contributions become measurable.

iostats

By default, **iostats** is enabled and the default value is **1**. Setting **iostats** value to **0** disables the gathering of I/O statistics for the device, which removes a small amount of overhead with the I/O path. Setting **iostats** to **0** might slightly improve performance for very high performance devices, such as certain NVMe solid-state storage devices. It is recommended to leave **iostats** enabled unless otherwise specified for the given storage model by the vendor.

If you disable **iostats**, the I/O statistics for the device are no longer present within the **/proc/diskstats** file. The content of **/sys/diskstats** file is the source of I/O information for monitoring I/O tools, such as **sar** or **iotop**. Therefore, if you disable the **iostats** parameter for a device, the device is no longer present in the output of I/O monitoring tools.

max_sectors_kb

Specifies the maximum size of an I/O request in kilobytes. The default value is **512** KB. The minimum value for this parameter is determined by the logical block size of the storage device. The maximum value for this parameter is determined by the value of the **max_hw_sectors_kb**.

Red Hat recommends **max_sectors_kb** to always be a multiple of the optimal I/O size and the internal erase block size. Use a value of **logical_block_size** for either parameter if they are zero or not specified by the storage device.

nomerges

Most workloads benefit from request merging. However, disabling merges can be useful for debugging purposes. By default, the **nomerges** parameter is set to **0**, which enables merging. To disable simple one-hit merging, set **nomerges** to **1**. To disable all types of merging, set **nomerges**

to **2**.

nr_requests

It is the maximum allowed number of the queued I/O. If the current I/O scheduler is **none**, this number can only be reduced; otherwise the number can be increased or reduced.

optimal_io_size

Some storage devices report an optimal I/O size through this parameter. If this value is reported, Red Hat recommends that applications issue I/O aligned to and in multiples of the optimal I/O size wherever possible.

read_ahead_kb

Defines the maximum number of kilobytes that the operating system may read ahead during a sequential read operation. As a result, the necessary information is already present within the kernel page cache for the next sequential read, which improves read I/O performance.

Device mappers often benefit from a high **read_ahead_kb** value. **128** KB for each device to be mapped is a good starting point, but increasing the **read_ahead_kb** value up to request queue's **max_sectors_kb** of the disk might improve performance in application environments where sequential reading of large files takes place.

rotational

Some solid-state disks do not correctly advertise their solid-state status, and are mounted as traditional rotational disks. Manually set the **rotational** value to **0** to disable unnecessary seek-reducing logic in the scheduler.

rq_affinity

The default value of the **rq_affinity** is **1**. It completes the I/O operations on one cpu core, which is in the same cpu group of the issued cpu core. To perform completions only on the processor that issued the I/O request, set the **rq_affinity** to **2**. To disable the mentioned two abilities, set it to **0**.

scheduler

To set the scheduler or scheduler preference order for a particular storage device, edit the **/sys/block/devname/queue/scheduler** file, where *devname* is the name of the device you want to configure.

CHAPTER 34. CONFIGURING AN OPERATING SYSTEM TO OPTIMIZE ACCESS TO NETWORK RESOURCES

This section describes how to configure the operating system to present optimized access to network resources across their workloads. Network performance problems are sometimes the result of hardware malfunction or faulty infrastructure. Resolving these issues is beyond the scope of this document.

The **Tuned** service provides a number of different profiles to improve performance in a number of specific use cases:

- **latency-performance**
- **network-latency**
- **network-throughput**

34.1. TOOLS FOR MONITORING AND DIAGNOSING PERFORMANCE ISSUES

The following are the available tools in Red Hat Enterprise Linux 8, which are used for monitoring system performance and diagnosing performance problems related to the networking subsystem:

- **ss** utility prints statistical information about sockets, enables administrators to assess device performance over time. By default, **ss** displays open non-listening TCP sockets that have established connections. Using command-line options, administrators can filter out statistics about specific sockets. Red Hat recommends **ss** over the deprecated **netstat** in Red Hat Enterprise Linux
- **ip** utility lets administrators manage and monitor routes, devices, routing policies, and tunnels. The **ip** monitor command can continuously monitor the state of devices, addresses, and routes. Use the **-j** option to display the output in JSON format, which can be further provided to other utilities to automate information processing.
- **dropwatch** is an interactive tool, provided by the **dropwatch** package. It monitors and records packets that are dropped by the kernel.
- **ethtool** utility enables administrators to view and edit network interface card settings. Use this tool to observe the statistics, such as the number of packets dropped by that device, of certain devices. Using the **ethtool -S device name** command, view the status of a specified device's counters of the device you want to monitor.
- **/proc/net/snmp** file displays data that the **snmp** agent uses for IP, ICMP, TCP and UDP monitoring and management. Examining this file on a regular basis helps administrators to identify unusual values and thereby identify potential performance problems. For example, an increase in UDP input errors (**InErrors**) in the **/proc/net/snmp** file can indicate a bottleneck in a socket receive queue.
- **nstat** tool monitors kernel SNMP and network interface statistics. This tool reads data from the **/proc/net/snmp** file and prints the information in a human readable format.
- By default, the **SystemTap** scripts, provided by the **systemtap-client** package are installed in the **/usr/share/systemtap/examples/network** directory:

- **nettop.stp**: Every 5 seconds, the script displays a list of processes (process identifier and command) with the number of packets sent and received and the amount of data sent and received by the process during that interval.
- **socket-trace.stp**: Instruments each of the functions in the Linux kernel's **net/socket.c** file, and displays trace data.
- **dropwatch.stp**: Every 5 seconds, the script displays the number of socket buffers freed at locations in the kernel. Use the **--all-modules** option to see symbolic names.
- **latencytap.stp**: This script records the effect that different types of latency have on one or more processes. It prints a list of latency types every 30 seconds, sorted in descending order by the total time the process or processes spent waiting. This can be useful for identifying the cause of both storage and network latency.

Red Hat recommends using the **--all-modules** option with this script to better enable the mapping of latency events. By default, this script is installed in the **/usr/share/systemtap/examples/profiling** directory.

- BPF Compiler Collection (BCC) is a library, which facilitates the creation of the extended Berkeley Packet Filter (**eBPF**) programs. The main utility of the **eBPF** programs is analyzing OS performance and network performance without experiencing overhead or security issues.

Additional resources

- **ss(8)**, **ethtool(8)**, **nettop(1)**, **ip(8)**, **dropwatch(1)**, and **systemtap(8)** man pages
- **/usr/share/systemtap/examples/network** directory

- [Configuring ethtool offload features](#)

34.2. BOTTLENECKS IN A PACKET RECEPTION

While the network stack is largely self-optimizing, there are a number of points during network packet processing that can become bottlenecks and reduce the performance.

The following are the issues that can cause bottleneck:

The buffer or ring buffer of the network card

The hardware buffer can be a bottleneck if the kernel drops a large number of packets. Use the **ethtool** utility for monitoring a system for dropped packets.

The hardware or software interrupt queues

Interrupts can increase latency and processor contention. For information on how the processor handles interrupts, see [Overview of an interrupt request](#), [Balancing interrupts manually](#), and [Setting the smp_affinity mask](#).

The socket receive queue of the application

A large number of packets that are not copied or by an increase in the UDP input errors (**InErrors**) in the **/proc/net/snmp** file, indicates a bottleneck in an application's receive queue.

If a the hardware buffer drops a large number of packets, the following are the few potential solutions:

Slow the input traffic

Filter the incoming traffic, reduce the number of joined multicast groups, or reduce the amount of broadcast traffic to decrease the rate at which the queue fills.

Resize the hardware buffer queue

Resize the hardware buffer queue: Reduce the number of packets being dropped by increasing the size of the queue so that it does not overflow as easily. You can modify the **rx/tx** parameters of the network device with the **ethtool** command:

ethtool --set-ring *device-name* value

Change the drain rate of the queue

- Decrease the rate at which the queue fills by filtering or dropping packets before they reach the queue, or by lowering the weight of the device. Filter incoming traffic or lower the network interface card's device weight to slow incoming traffic.
The device weight refers to the number of packets a device can receive at one time in a single scheduled processor access. You can increase the rate at which a queue is drained by increasing its device weight that is controlled by the **dev_weight** kernel setting. To temporarily alter this parameter, change the contents of the **/proc/sys/net/core/dev_weight** file, or to permanently alter, use the **sysctl** command, which is provided by the **procps-ng** package.
- Increase the length of the application's socket queue: This is typically the easiest way to improve the drain rate of a socket queue, but it is unlikely to be a long-term solution. If a socket queue receives a limited amount of traffic in bursts, increasing the depth of the socket queue to match the size of the bursts of traffic may prevent packets from being dropped. To increase the depth of a queue, increase the size of the socket receive buffer by making either of the following changes:
 - Increase the value of the **/proc/sys/net/core/rmem_default** parameter: This parameter controls the default size of the receive buffer used by sockets. This value must be smaller than or equal to the value of the **/proc/sys/net/core/rmem_max** parameter.
 - Use the **setsockopt** to configure a larger **SO_RCVBUF** value: This parameter controls the maximum size in bytes of a socket's receive buffer. Use the **getsockopt** system call to determine the current value of the buffer.

Altering the drain rate of a queue is usually the simplest way to mitigate poor network performance. However, increasing the number of packets that a device can receive at one time uses additional processor time, during which no other processes can be scheduled, so this can cause other performance problems.

Additional resources

- **ss(8)**, **socket(7)**, and **ethtool(8)** man pages
- **/proc/net/snmp** file

34.3. BUSY POLLING

If analysis reveals high latency, your system may benefit from the poll-based rather than interrupt-based packet receipt.

Busy polling helps to reduce latency in the network receive path by allowing socket layer code to poll the receive queue of a network device, and disables network interrupts. This removes delays caused by the

interrupt and the resultant context switch. However, it also increases CPU utilization. Busy polling also prevents the CPU from sleeping, which can incur additional power consumption. Busy polling behavior is supported by all the device drivers.

Additional resources

- [Enabling busy polling](#)

34.3.1. Enabling busy polling

By default, the busy polling is disabled. This procedure describes how to enable busy polling.

Procedure

1. Ensure if the **CONFIG_NET_RX_BUSY_POLL** compilation option is enabled:

```
# cat /boot/config-$(uname -r) | grep CONFIG_NET_RX_BUSY_POLL
CONFIG_NET_RX_BUSY_POLL=y
```

2. Enable busy polling

- a. To enable busy polling on specific sockets, set the **sysctl.net.core.busy_poll** kernel value to a value other than **0**:

```
# echo "net.core.busy_poll=50" > /etc/sysctl.d/95-enable-busy-polling-for-sockets.conf
# sysctl -p /etc/sysctl.d/95-enable-busy-polling-for-sockets.conf
```

This parameter controls the number of microseconds to wait for packets on the socket poll and select **syscalls**. Red Hat recommends a value of **50**.

- b. Add the **SO_BUSY_POLL** socket option to the socket.
- c. To enable busy polling globally, set the **sysctl.net.core.busy_read** to a value other than **0**:

```
# echo "net.core.busy_read=50" > /etc/sysctl.d/95-enable-busy-polling-globally.conf
# sysctl -p /etc/sysctl.d/95-enable-busy-polling-globally.conf
```

The **net.core.busy_read** parameter controls the number of microseconds to wait for packets on the device queue for socket reads. It also sets the default value of the **SO_BUSY_POLL** option. Red Hat recommends a value of **50** for a small number of sockets, and a value of **100** for large numbers of sockets. For extremely large numbers of sockets, for example more than several hundred, use the **epoll** system call instead.

Verification steps

- Verify if the busy poll is enabled

```
# ethtool -k device | grep "busy-poll"
busy-poll: on [fixed]

# cat /proc/sys/net/core/busy_read
50
```

Additional resources

- **ethtool(8)**, **socket(7)**, **sysctl(8)**, and **sysctl.conf(5)** man pages
- [Configuring ethtool offload features](#)

34.4. RECEIVE-SIDE SCALING

Receive-Side Scaling (RSS), also known as multi-queue receive, distributes network receive processing across several hardware-based receive queues, allowing inbound network traffic to be processed by multiple CPUs. RSS can be used to relieve bottlenecks in receive interrupt processing caused by overloading a single CPU, and to reduce network latency. By default, RSS is enabled.

The number of queues or the CPUs that should process network activity for RSS are configured in the appropriate network device driver:

- For the **bnx2x** driver, it is configured in the **num_queues** parameter.
- For the **sfc** driver, it is configured in the **rss_cpus** parameter.

Regardless, it is typically configured in the **/sys/class/net/device/queues/rx-queue/** directory, where **device** is the name of the network device (such as **enp1s0**) and **rx-queue** is the name of the appropriate receive queue.

The **irqbalance** daemon can be used in conjunction with RSS to reduce the likelihood of cross-node memory transfers and cache line bouncing. This lowers the latency of processing network packets.

34.4.1. Viewing the interrupt request queues

When configuring Receive-Side Scaling (RSS), Red Hat recommends limiting the number of queues to one per physical CPU core. Hyper-threads are often represented as separate cores in analysis tools, but configuring queues for all cores including logical cores such as hyper-threads has not proven beneficial to network performance.

When enabled, RSS distributes network processing equally between available CPUs based on the amount of processing each CPU has queued. However, use the **--show-rxfh-indir** and **--set-rxfh-indir** parameters of the **ethtool** utility, to modify how RHEL distributes network activity, and weigh certain types of network activity as more important than others.

This procedure describes how to view the interrupt request queues.

Procedure

- To determine whether your network interface card supports RSS, check whether multiple interrupt request queues are associated with the interface in **/proc/interrupts**:

```
# egrep 'CPU|p1p1' /proc/interrupts
CPU0  CPU1  CPU2  CPU3  CPU4  CPU5
89:  40187    0    0    0    0    0 IR-PCI-MSI-edge p1p1-0
90:    0   790    0    0    0    0 IR-PCI-MSI-edge p1p1-1
91:    0    0  959    0    0    0 IR-PCI-MSI-edge p1p1-2
92:    0    0    0 3310    0    0 IR-PCI-MSI-edge p1p1-3
93:    0    0    0    0  622    0 IR-PCI-MSI-edge p1p1-4
94:    0    0    0    0    0 2475 IR-PCI-MSI-edge p1p1-5
```

The output shows that the NIC driver created 6 receive queues for the **p1p1** interface (**p1p1-0** through **p1p1-5**). It also shows how many interrupts were processed by each queue, and which

CPU serviced the interrupt. In this case, there are 6 queues because by default, this particular NIC driver creates one queue per CPU, and this system has 6 CPUs. This is a fairly common pattern among NIC drivers.

- To list the interrupt request queue for a PCI device with the address **0000:01:00.0**:

```
# ls -l /sys/devices/*/0000:01:00.0/msi_irqs
101
102
103
104
105
106
107
108
109
```

34.5. RECEIVE PACKET STEERING

Receive Packet Steering (RPS) is similar to Receive-Side Scaling (RSS) in that it is used to direct packets to specific CPUs for processing. However, RPS is implemented at the software level, and helps to prevent the hardware queue of a single network interface card from becoming a bottleneck in network traffic.

RPS has several advantages over hardware-based RSS:

- RPS can be used with any network interface card.
- It is easy to add software filters to RPS to deal with new protocols.
- RPS does not increase the hardware interrupt rate of the network device. However, it does introduce inter-processor interrupts.

RPS is configured per network device and receive queue, in the **/sys/class/net/device/queues/rx-queue/rps_cpus** file, where *device* is the name of the network device, such as `enp1s0` and *rx-queue* is the name of the appropriate receive queue, such as `rx-0`.

The default value of the **rps_cpus** file is 0. This disables RPS, and the CPU handles the network interrupt and also processes the packet. To enable RPS, configure the appropriate **rps_cpus** file with the CPUs that should process packets from the specified network device and receive queue.

The **rps_cpus** files use comma-delimited CPU bitmaps. Therefore, to allow a CPU to handle interrupts for the receive queue on an interface, set the value of their positions in the bitmap to 1. For example, to handle interrupts with CPUs **0**, **1**, **2**, and **3**, set the value of the **rps_cpus** to **f**, which is the hexadecimal value for **15**. In binary representation, **15** is **00001111 (1+2+4+8)**.

For network devices with single transmit queues, best performance can be achieved by configuring RPS to use CPUs in the same memory domain. On non-NUMA systems, this means that all available CPUs can be used. If the network interrupt rate is extremely high, excluding the CPU that handles network interrupts may also improve performance.

For network devices with multiple queues, there is typically no benefit to configure both RPS and RSS, as RSS is configured to map a CPU to each receive queue by default. However, RPS can still be beneficial if there are fewer hardware queues than CPUs, and RPS is configured to use CPUs in the same memory domain.

34.6. RECEIVE FLOW STEERING

Receive Flow Steering (RFS) extends Receive Packet Steering (RPS) behavior to increase the CPU cache hit rate and thereby reduce network latency. Where RPS forwards packets based solely on queue length, RFS uses the RPS back end to calculate the most appropriate CPU, then forwards packets based on the location of the application consuming the packet. This increases CPU cache efficiency.

Data received from a single sender is not sent to more than one CPU. If the amount of data received from a single sender is greater than a single CPU can handle, configure a larger frame size to reduce the number of interrupts and therefore the amount of processing work for the CPU. Alternatively, consider NIC offload options or faster CPUs.

Consider using **numactl** or **taskset** in conjunction with RFS to pin applications to specific cores, sockets, or NUMA nodes. This can help prevent packets from being processed out of order.

34.6.1. Enabling Receive Flow Steering

By default, Receive Flow Steering (RFS) is disabled. This procedure describes how to enable RFS.

Procedure

1. Set the value of the **net.core.rps_sock_flow_entries** kernel value to the maximum expected number of concurrently active connections:

```
# echo "net.core.rps_sock_flow_entries=32768" > /etc/sysctl.d/95-enable-rps.conf
```

NOTE

Red Hat recommends a value of **32768** for moderate server loads. All values entered are rounded up to the nearest power of **2** in practice.

2. Persistently set the value of the **net.core.rps_sock_flow_entries**:

```
# sysctl -p /etc/sysctl.d/95-enable-rps.conf
```

3. To temporarily set the value of the **sys/class/net/device/queues/rx-queue/rps_flow_cnt** file to the value of the $(\text{rps_sock_flow_entries}/N)$, where N is the number of receive queues on a device:

```
# echo 2048 > /sys/class/net/device/queues/rx-queue/rps_flow_cnt
```

Replace *device* with the name of the network device you wish to configure (for example, `enp1s0`), and *rx-queue* with the receive queue you wish to configure (for example, `rx-0`).

Replace N with the number of configured receive queues. For example, if the **rps_flow_entries** is set to **32768** and there are **16** configured receive queues, the **rps_flow_cnt = 32768/16 = 2048** (that is, **rps_flow_cnt = rps_flow_entries/N**).

For single-queue devices, the value of **rps_flow_cnt** is the same as the value of **rps_sock_flow_entries**.

4. Persistently enable RFS on all network devices, create the **/etc/udev/rules.d/99-persistent-net.rules** file, and add the following content:

```
SUBSYSTEM=="net", ACTION=="add", RUN{program}+="/bin/bash -c 'for x in
/sys/$DEVPATH/queues/rx-*; do echo 2048 > $x/rps_flow_cnt; done'"
```

5. Optional: To enable RPS on a specific network device:

```
SUBSYSTEM=="net", ACTION=="move", NAME="device name" RUN{program}+="/bin/bash
-c 'for x in /sys/$DEVPATH/queues/rx-*; do echo 2048 > $x/rps_flow_cnt; done'"
```

Replace *device name* with the actual network device name.

Verification steps

- Verify if RFS is enabled:

```
# cat /proc/sys/net/core/rps_sock_flow_entries
32768

# cat /sys/class/net/device/queues/rx-queue/rps_flow_cnt
2048
```

Additional resources

- **sysctl(8)** man page

34.7. ACCELERATED RFS

Accelerated RFS boosts the speed of Receive Flow Steering (RFS) by adding hardware assistance. Like RFS, packets are forwarded based on the location of the application consuming the packet.

Unlike traditional RFS, however, packets are sent directly to a CPU that is local to the thread consuming the data:

- either the CPU that is executing the application
- or a CPU local to that CPU in the cache hierarchy

Accelerated RFS is only available if the following conditions are met:

- NIC must support the accelerated RFS. Accelerated RFS is supported by cards that export the **ndo_rx_flow_steer()** **net_device** function. Check the NIC's data sheet to ensure if this feature is supported.
- **ntuple** filtering must be enabled. For information on how to enable these filters, see [Enabling the ntuple filters](#).

Once these conditions are met, CPU to queue mapping is deduced automatically based on traditional RFS configuration. That is, CPU to queue mapping is deduced based on the IRQ affinities configured by the driver for each receive queue. For more information on enabling the traditional RFS, see [Enabling Receive Flow Steering](#).

34.7.1. Enabling the ntuple filters

The **ntuple** filtering must be enabled. Use the **ethtool -k** command to enable the **ntuple** filters.

Procedure

1. Display the current status of the **ntuple** filter:

```
# ethtool -k enp1s0 | grep ntuple-filters  
  
ntuple-filters: off
```

2. Enable the **ntuple** filters:

```
# ethtool -k enp1s0 ntuple on
```

NOTE

If the output is **ntuple-filters: off [fixed]**, then the **ntuple** filtering is disabled and you cannot configure it:

```
# ethtool -k enp1s0 | grep ntuple-filters  
ntuple-filters: off [fixed]
```

Verification steps

- Ensure if **ntuple** filters are enabled:

```
# ethtool -k enp1s0 | grep ntuple-filters  
ntuple-filters: on
```

Additional resources

- **ethtool(8)** man page

CHAPTER 35. CONFIGURING AN OPERATING SYSTEM TO OPTIMIZE MEMORY ACCESS

This section describes how to configure the operating system to optimize memory access across workloads, and the tools you can use to do so.

35.1. TOOLS FOR MONITORING AND DIAGNOSING SYSTEM MEMORY ISSUES

The following tools are available in Red Hat Enterprise Linux 8 for monitoring system performance and diagnosing performance problems related to system memory:

- **vmstat** tool, provided by the **procps-ng** package, displays reports of a system's processes, memory, paging, block I/O, traps, disks, and CPU activity. It provides an instantaneous report of the average of these events since the machine was last turned on, or since the previous report.
- **valgrind** framework provides instrumentation to user-space binaries. Install this tool, using the **yum install valgrind** command. It includes a number of tools, that you can use to profile and analyze program performance, such as:
 - **memcheck** option is the default **valgrind** tool. It detects and reports on a number of memory errors that can be difficult to detect and diagnose, such as:
 - Memory access that should not occur
 - Undefined or uninitialized value use
 - Incorrectly freed heap memory
 - Pointer overlap
 - Memory leaks

NOTE

Memcheck can only report these errors, it cannot prevent them from occurring. However, **memcheck** logs an error message immediately before the error occurs.

- **cachegrind** option simulates application interaction with a system's cache hierarchy and branch predictor. It gathers statistics for the duration of application's execution and outputs a summary to the console.
- **massif** option measures the heap space used by a specified application. It measures both useful space and any additional space allocated for bookkeeping and alignment purposes.

Additional resources

- **vmstat(8)** and **valgrind(1)** man pages
- **/usr/share/doc/valgrind-version/valgrind_manual.pdf** file

35.2. OVERVIEW OF A SYSTEM'S MEMORY

The Linux Kernel is designed to maximize the utilization of a system's memory resources (RAM). Due to these design characteristics, and depending on the memory requirements of the workload, part of the system's memory is in use within the kernel on behalf of the workload, while a small part of the memory is free. This free memory is reserved for special system allocations, and for other low or high priority system services.

The rest of the system's memory is dedicated to the workload itself, and divided into the following two categories:

File memory

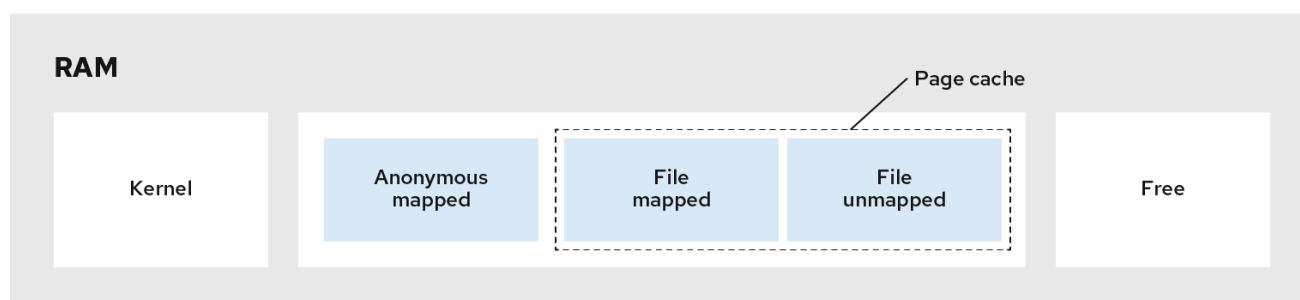

Pages added in this category represent parts of files in permanent storage. These pages, from the page cache, can be mapped or unmapped in an application's address spaces. You can use applications to map files into their address space using the **mmap** system calls, or to operate on files via the buffered I/O read or write system calls.

Buffered I/O system calls, as well as applications that map pages directly, can re-utilize unmapped pages. As a result, these pages are stored in the cache by the kernel, especially when the system is not running any memory intensive tasks, to avoid re-issuing costly I/O operations over the same set of pages.

Anonymous memory

Pages in this category are in use by a dynamically allocated process, or are not related to files in permanent storage. This set of pages back up the in-memory control structures of each task, such as the application stack and heap areas.

Figure 35.1. Memory usage patterns

133_RHEL_0121

35.3. VIRTUAL MEMORY PARAMETERS

The virtual memory parameters are listed in the **/proc/sys/vm** directory.

The following are the available virtual memory parameters:

vm.dirty_ratio

Is a percentage value. When this percentage of the total system memory is modified, the system begins writing the modifications to the disk with the **pdflush** operation. The default value is **20** percent.

vm.dirty_background_ratio

A percentage value. When this percentage of total system memory is modified, the system begins writing the modifications to the disk in the background. The default value is **10** percent.

vm.overcommit_memory

Defines the conditions that determine whether a large memory request is accepted or denied. The default value is **0**.

By default, the kernel performs heuristic memory overcommit handling by estimating the amount of memory available and failing requests that are too large. However, since memory is allocated using a heuristic rather than a precise algorithm, overloading memory is possible with this setting.

Setting the **overcommit_memory** parameter's value:

- When this parameter is set to **1**, the kernel performs no memory overcommit handling. This increases the possibility of memory overload, but improves performance for memory-intensive tasks.
- When this parameter is set to **2**, the kernel denies requests for memory equal to or larger than the sum of the total available swap space and the percentage of physical RAM specified in the **overcommit_ratio**. This reduces the risk of overcommitting memory, but is recommended only for systems with swap areas larger than their physical memory.

vm.overcommit_ratio

Specifies the percentage of physical RAM considered when **overcommit_memory** is set to **2**. The default value is **50**.

vm.max_map_count

Defines the maximum number of memory map areas that a process can use. The default value is **65530**. Increase this value if your application needs more memory map areas.

vm.min_free_kbytes

Sets the size of the reserved free pages pool. It is also responsible for setting the **min_page**, **low_page**, and **high_page** thresholds that govern the behavior of the Linux kernel's page reclaim algorithms. It also specifies the minimum number of kilobytes to keep free across the system. This calculates a specific value for each low memory zone, each of which is assigned a number of reserved free pages in proportion to their size.

Setting the **vm.min_free_kbytes** parameter's value:

- Increasing the parameter value effectively reduces the application working set usable memory. Therefore, you might want to use it for only kernel-driven workloads, where driver buffers need to be allocated in atomic contexts.
- Decreasing the parameter value might render the kernel unable to service system requests, if memory becomes heavily contended in the system.

WARNING

Extreme values can be detrimental to the system's performance. Setting the **vm.min_free_kbytes** to an extremely low value prevents the system from reclaiming memory effectively, which can result in system crashes and failure to service interrupts or other kernel services. However, setting **vm.min_free_kbytes** too high considerably increases system reclaim activity, causing allocation latency due to a false direct reclaim state. This might cause the system to enter an out-of-memory state immediately.

The **vm.min_free_kbytes** parameter also sets a page reclaim watermark, called **min_pages**. This watermark is used as a factor when determining the two other memory watermarks, **low_pages**, and **high_pages**, that govern page reclaim algorithms.

/proc/*PID*/oom_adj

In the event that a system runs out of memory, and the **panic_on_oom** parameter is set to **0**, the **oom_killer** function kills processes, starting with the process that has the highest **oom_score**, until the system recovers.

The **oom_adj** parameter determines the **oom_score** of a process. This parameter is set per process identifier. A value of **-17** disables the **oom_killer** for that process. Other valid values range from **-16** to **15**.

NOTE

Processes created by an adjusted process inherit the **oom_score** of that process.

vm.swappiness

The swappiness value, ranging from **0** to **100**, controls the degree to which the system favors reclaiming memory from the anonymous memory pool, or the page cache memory pool.

Setting the **swappiness** parameter's value:

- Higher values favor file-mapped driven workloads while swapping out the less actively accessed processes' anonymous mapped memory of RAM. This is useful for file-servers or streaming applications that depend on data, from files in the storage, to reside on memory to reduce I/O latency for the service requests.
- Low values favor anonymous-mapped driven workloads while reclaiming the page cache (file mapped memory). This setting is useful for applications that do not depend heavily on the file system information, and heavily utilize dynamically allocated and private memory, such as mathematical and number crunching applications, and few hardware virtualization supervisors like QEMU.

The default value of the **vm.swappiness** parameter is **30**.

WARNING

Setting the **vm.swappiness** to **0** aggressively avoids swapping anonymous memory out to a disk, this increases the risk of processes being killed by the **oom_killer** function when under memory or I/O intensive workloads.

Additional resources

- **sysctl(8)** man page
- [Setting memory-related kernel parameters](#)

35.4. FILE SYSTEM PARAMETERS

The file system parameters are listed in the `/proc/sys/fs` directory. The following are the available file system parameters:

aio-max-nr

Defines the maximum allowed number of events in all active asynchronous input/output contexts. The default value is **65536**, and modifying this value does not pre-allocate or resize any kernel data structures.

file-max

Determines the maximum number of file handles for the entire system. The default value on Red Hat Enterprise Linux 8 is either **8192** or one tenth of the free memory pages available at the time the kernel starts, whichever is higher.

Raising this value can resolve errors caused by a lack of available file handles.

Additional resources

- **sysctl(8)** man page

35.5. KERNEL PARAMETERS

The default values for the kernel parameters are located in the `/proc/sys/kernel/` directory. These values are calculated by the kernel at boot time depending on the available system resources.

The following are the available kernel parameters used to set up limits for the **msg*** and **shm*** System V IPC (**sysvipc**) system calls:

msgmax

Defines the maximum allowed size in bytes of any single message in a message queue. This value must not exceed the size of the queue (**msgmnb**). Use the **sysctl msgmax** command to determine the current **msgmax** value on your system.

msgmnb

Defines the maximum size in bytes of a single message queue. Use the **sysctl msgmnb** command to determine the current **msgmnb** value on your system.

msgmni

Defines the maximum number of message queue identifiers, and therefore the maximum number of queues. Use the **sysctl msgmni** command to determine the current **msgmni** value on your system.

shmall

Defines the total amount of shared memory pages that can be used on the system at one time. For example, a page is **4096** bytes on the AMD64 and Intel 64 architecture. Use the **sysctl shmall** command to determine the current **shmall** value on your system.

shmmax

Defines the maximum size in bytes of a single shared memory segment allowed by the kernel. Use the **sysctl shmmax** command to determine the current **shmmax** value on your system.

shmmni

Defines the system-wide maximum number of shared memory segments. The default value is **4096** on all systems.

Additional resources

- **sysvipc(7)** and **sysctl(8)** man pages

35.6. SETTING MEMORY-RELATED KERNEL PARAMETERS

Setting a parameter temporarily is useful for determining the effect the parameter has on a system. You can later set the parameter persistently when you are sure that the parameter value has the desired effect.

This procedure describes how to set a memory-related kernel parameter temporarily and persistently.

Procedure

- To temporarily set the memory-related kernel parameters, edit the respective files in the **/proc** file system.

For example, to temporarily set the **vm.overcommit_memory** parameter to **1**:

```
# echo 1 > /proc/sys/vm/overcommit_memory
# sysctl -w vm.overcommit_memory=1
```

- To persistently set the memory-related kernel parameter, use the **sysctl** tool.
For example, to persistently set the **vm.overcommit_memory** parameter to **1**:

- Add the following content in the **/etc/sysctl.conf** file:

```
vm.overcommit_memory=1
```

- Reload the **sysctl** settings from the **/etc/sysctl.conf** file:

```
# sysctl -p
```

Additional resources

- **sysctl(8)** man page

CHAPTER 36. CONFIGURING HUGE PAGES

Physical memory is managed in fixed-size chunks called pages. On the x86_64 architecture, supported by Red Hat Enterprise Linux 8, the default size of a memory page is **4 KB**. This default page size has proved to be suitable for general-purpose operating systems, such as Red Hat Enterprise Linux, which supports many different kinds of workloads.

However, specific applications can benefit from using larger page sizes in certain cases. For example, an application that works with a large and relatively fixed data set of hundreds of megabytes or even dozens of gigabytes can have performance issues when using **4 KB** pages. Such data sets can require a huge amount of **4 KB** pages, which can lead to overhead in the operating system and the CPU.

This section provides information about huge pages available in Red Hat Enterprise Linux 8 and how you can configure them.

36.1. AVAILABLE HUGE PAGE FEATURES

With Red Hat Enterprise Linux 8, you can use huge pages for applications that work with big data sets, and improve the performance of such applications.

The following are the huge page methods, which are supported in Red Hat Enterprise Linux 8:

HugeTLB pages

HugeTLB pages are also called static huge pages. There are two ways of reserving HugeTLB pages:

- **At boot time:** It increases the possibility of success because the memory has not yet been significantly fragmented. However, on NUMA machines, the number of pages is automatically split among the NUMA nodes. For more information on parameters that influence HugeTLB page behavior at boot time, see [Parameters for reserving HugeTLB pages at boot time](#) and how to use these parameters to configure HugeTLB pages at boot time, see [Configuring HugeTLB at boot time](#).
- **At run time:** It allows you to reserve the huge pages per NUMA node. If the run-time reservation is done as early as possible in the boot process, the probability of memory fragmentation is lower. For more information on parameters that influence HugeTLB page behavior at boot time, see [Parameters for reserving HugeTLB pages at run time](#) and how to use these parameters to configure HugeTLB pages at boot time, see [Configuring HugeTLB at run time](#).

Transparent HugePages (THP)

With THP, the kernel automatically assigns huge pages to processes, and therefore there is no need to manually reserve the static huge pages. The following are the two modes of operation in THP:

- **system-wide:** Here, the kernel tries to assign huge pages to a process whenever it is possible to allocate the huge pages and the process is using a large contiguous virtual memory area.
- **per-process:** Here, the kernel only assigns huge pages to the memory areas of individual processes which you can specify using the **madvise()** system call.

NOTE

The THP feature only supports **2 MB** pages.

For information on enabling and disabling THP, see [For more information on parameters that influence HugeTLB page behavior at boot time](#), see [Enabling transparent hugepages](#) and [Disabling transparent hugepages](#).

36.2. PARAMETERS FOR RESERVING HUGETLB PAGES AT BOOT TIME

Use the following parameters to influence HugeTLB page behavior at boot time.

Table 36.1. Parameters used to configure HugeTLB pages at boot time

Parameter	Description	Default value
hugepages	<p>Defines the number of persistent huge pages configured in the kernel at boot time.</p> <p>In a NUMA system, huge pages, that have this parameter defined, are divided equally between nodes.</p> <p>You can assign huge pages to specific nodes at runtime by changing the value of the nodes in the /sys/devices/system/node/node_id/hugepages/hugepages-size/nr_hugepages file.</p>	<p>The default value is 0.</p> <p>To update this value at boot, change the value of this parameter in the /proc/sys/vm/nr_hugepages file.</p>
hugepagesz	Defines the size of persistent huge pages configured in the kernel at boot time.	Valid values are 2 MB and 1 GB . The default value is 2 MB .
default_hugepagesz	Defines the default size of persistent huge pages configured in the kernel at boot time.	Valid values are 2 MB and 1 GB . The default value is 2 MB .

36.3. CONFIGURING HUGETLB AT BOOT TIME

The page size, which the HugeTLB subsystem supports, depends on the architecture. The x86_64 architecture supports **2 MB** huge pages and **1 GB** gigantic pages.

This procedure describes how to reserve a **1 GB** page at boot time.

Procedure

1. Create a HugeTLB pool for **1 GB** pages by appending the following line to the kernel command-line options in the **/etc/default/grub** file as root:

```
default_hugepagesz=1G hugepagesz=1G
```

2. Regenerate the **GRUB2** configuration using the edited default file:

- a. If your system uses BIOS firmware, execute the following command:

```
# grub2-mkconfig -o /boot/grub2/grub.cfg
```

- b. If your system uses UEFI framework, execute the following command:

```
# grub2-mkconfig -o /boot/efi/EFI/redhat/grub.cfg
```

3. Create a new file called **hugetlb-gigantic-pages.service** in the **/usr/lib/systemd/system/** directory and add the following content:

```
[Unit]
Description=HugeTLB Gigantic Pages Reservation
DefaultDependencies=no
Before=dev-hugepages.mount
ConditionPathExists=/sys/devices/system/node
ConditionKernelCommandLine=hugepagesz=1G

[Service]
Type=oneshot
RemainAfterExit=yes
ExecStart=/usr/lib/systemd/hugetlb-reserve-pages.sh

[Install]
WantedBy=sysinit.target
```

4. Create a new file called **hugetlb-reserve-pages.sh** in the **/usr/lib/systemd/** directory and add the following content:

While adding the following content, replace *number_of_pages* with the number of 1GB pages you want to reserve, and *node* with the name of the node on which to reserve these pages.

```
#!/bin/sh

nodes_path=/sys/devices/system/node/
if [ ! -d $nodes_path ]; then
    echo "ERROR: $nodes_path does not exist"
    exit 1
fi

reserve_pages()
{
    echo $1 > $nodes_path/$2/hugepages/hugepages-1048576kB/nr_hugepages
}

reserve_pages number_of_pages node
```

For example, to reserve two **1 GB** pages on *node0* and one 1GB page on *node1*, replace the *number_of_pages* with 2 for *node0* and 1 for *node1*:

```
reserve_pages 2 node0
reserve_pages 1 node1
```

5. Create an executable script:

```
# chmod +x /usr/lib/systemd/hugetlb-reserve-pages.sh
```

6. Enable early boot reservation:

```
# systemctl enable hugetlb-gigantic-pages
```

NOTE

- You can try reserving more 1GB pages at runtime by writing to **nr_hugepages** at any time. However, such reservations can fail due to memory fragmentation. The most reliable way to reserve **1 GB** pages is by using this **hugetlb-reserve-pages.sh** script, which runs early during boot.
- Reserving static huge pages can effectively reduce the amount of memory available to the system, and prevents it from properly utilizing its full memory capacity. Although a properly sized pool of reserved huge pages can be beneficial to applications that utilize it, an oversized or unused pool of reserved huge pages will eventually be detrimental to overall system performance. When setting a reserved huge page pool, ensure that the system can properly utilize its full memory capacity.

Additional resources

- **systemd.service(5)** man page
- **/usr/share/doc/kernel-doc-kernel_version/Documentation/vm/hugetlbpage.txt** file

36.4. PARAMETERS FOR RESERVING HUGETLB PAGES AT RUN TIME

Use the following parameters to influence HugeTLB page behavior at run time.

Table 36.2. Parameters used to configure HugeTLB pages at run time

Parameter	Description	File name
nr_hugepages	Defines the number of huge pages of a specified size assigned to a specified NUMA node.	/sys/devices/system/node/node_id/hugepages/hugepages-size/nr_hugepages

Parameter	Description	File name
nr_overcommit_hugepages	<p>Defines the maximum number of additional huge pages that can be created and used by the system through overcommitting memory.</p> <p>Writing any non-zero value into this file indicates that the system obtains that number of huge pages from the kernel's normal page pool if the persistent huge page pool is exhausted. As these surplus huge pages become unused, they are then freed and returned to the kernel's normal page pool.</p>	/proc/sys/vm/nr_overcommit_hugepages

36.5. CONFIGURING HUGETLB AT RUN TIME

This procedure describes how to add *20 2048 kB* huge pages to *node2*.

To reserve pages based on your requirements, replace:

- *20* with the number of huge pages you wish to reserve,
- *2048kB* with the size of the huge pages,
- *node2* with the node on which you wish to reserve the pages.

Procedure

1. Display the memory statistics:

```
# numastat -cm | egrep 'Node|Huge'
      Node 0 Node 1 Node 2 Node 3 Total add
AnonHugePages      0   2   0   8   10
HugePages_Total    0   0   0   0   0
HugePages_Free     0   0   0   0   0
HugePages_Surp     0   0   0   0   0
```

2. Add the number of huge pages of a specified size to the node:

```
# echo 20 > /sys/devices/system/node/node2/hugepages/hugepages-2048kB/nr_hugepages
```

Verification steps

- Ensure that the number of huge pages are added:

```
# numastat -cm | egrep 'Node|Huge'
      Node 0 Node 1 Node 2 Node 3 Total
AnonHugePages      0   2   0   8   10
```

HugePages_Total	0	0	40	0	40
HugePages_Free	0	0	40	0	40
HugePages_Surp	0	0	0	0	0

Additional resources

- **numastat(8)** man page

36.6. ENABLING TRANSPARENT HUGE PAGES

THP is enabled by default in Red Hat Enterprise Linux 8. However, you can enable or disable THP.

This procedure describes how to enable THP.

Procedure

1. Check the current status of THP:

```
# cat /sys/kernel/mm/transparent_hugepage/enabled
```

2. Enable THP:

```
# echo always > /sys/kernel/mm/transparent_hugepage/enabled
```

3. To prevent applications from allocating more memory resources than necessary, disable the system-wide transparent huge pages and only enable them for the applications that explicitly request it through the **madvise**:

```
# echo madvise > /sys/kernel/mm/transparent_hugepage/enabled
```

NOTE

Sometimes, providing low latency to short-lived allocations has higher priority than immediately achieving the best performance with long-lived allocations. In such cases, you can disable direct compaction while leaving THP enabled.

Direct compaction is a synchronous memory compaction during the huge page allocation. Disabling direct compaction provides no guarantee of saving memory, but can decrease the risk of higher latencies during frequent page faults. Note that if the workload benefits significantly from THP, the performance decreases. Disable direct compaction:

```
# echo madvise > /sys/kernel/mm/transparent_hugepage/defrag
```

Additional resources

- **madvise(2)** man page
- [Disabling transparent hugepages](#).

36.7. DISABLING TRANSPARENT HUGE PAGES

THP is enabled by default in Red Hat Enterprise Linux 8. However, you can enable or disable THP.

This procedure describes how to disable THP.

Procedure

1. Check the current status of THP:

```
# cat /sys/kernel/mm/transparent_hugepage/enabled
```

2. Disable THP:

```
# echo never > /sys/kernel/mm/transparent_hugepage/enabled
```

36.8. IMPACT OF PAGE SIZE ON TRANSLATION LOOKASIDE BUFFER SIZE

Reading address mappings from the page table is time-consuming and resource-expensive, so CPUs are built with a cache for recently-used addresses, called the Translation Lookaside Buffer (TLB). However, the default TLB can only cache a certain number of address mappings.

If a requested address mapping is not in the TLB, called a TLB miss, the system still needs to read the page table to determine the physical to virtual address mapping. Because of the relationship between application memory requirements and the size of pages used to cache address mappings, applications with large memory requirements are more likely to suffer performance degradation from TLB misses than applications with minimal memory requirements. It is therefore important to avoid TLB misses wherever possible.

Both HugeTLB and Transparent Huge Page features allow applications to use pages larger than **4 KB**. This allows addresses stored in the TLB to reference more memory, which reduces TLB misses and improves application performance.

CHAPTER 37. GETTING STARTED WITH SYSTEMTAP

As a system administrator, you can use SystemTap to identify underlying causes of a bug or performance problem on a running Linux system.

As an application developer, you can use SystemTap to monitor in fine detail how your application behaves within the Linux system.

37.1. THE PURPOSE OF SYSTEMTAP

SystemTap is a tracing and probing tool that you can use to study and monitor the activities of your operating system (particularly, the kernel) in fine detail. SystemTap provides information similar to the output of tools such as **netstat**, **ps**, **top**, and **iostat**. However, SystemTap provides more filtering and analysis options for collected information. In SystemTap scripts, you specify the information that SystemTap gathers.

SystemTap aims to supplement the existing suite of Linux monitoring tools by providing users with the infrastructure to track kernel activity and combining this capability with two attributes:

Flexibility

the SystemTap framework enables you to develop simple scripts for investigating and monitoring a wide variety of kernel functions, system calls, and other events that occur in kernel space. With this, SystemTap is not so much a tool as it is a system that allows you to develop your own kernel-specific forensic and monitoring tools.

Ease-of-Use

SystemTap enables you to monitor kernel activity without having to recompile the kernel or reboot the system.

37.2. INSTALLING SYSTEMTAP

To begin using SystemTap, install the required packages. To use SystemTap on more than one kernel where a system has multiple kernels installed, install the corresponding required kernel packages for *each* kernel version.

Prerequisites

- You have enabled debug repositories as described in [Enabling debug and source repositories](#).

Procedure

1. Install the required SystemTap packages:

```
# yum install systemtap
```

2. Install the required kernel packages:

- a. Using **stap-prep**:

```
# stap-prep
```

- b. If **stap-prep** does not work, install the required kernel packages manually:

```
# yum install kernel-debuginfo-$(uname -r) kernel-debuginfo-common-$(uname -i)-
$(uname -r) kernel-devel-$(uname -r)
```

\$(uname -i) is automatically replaced with the hardware platform of your system and **\$(uname -r)** is automatically replaced with the version of your running kernel.

Verification steps

- If the kernel to be probed with SystemTap is currently in use, test if your installation was successful:

```
# stap -v -e 'probe kernel.function("vfs_read") {printf("read performed\n"); exit();}'
```

A successful SystemTap deployment results in an output similar to the following:

```
Pass 1: parsed user script and 45 library script(s) in 340usr/0sys/358real ms.
Pass 2: analyzed script: 1 probe(s), 1 function(s), 0 embed(s), 0 global(s) in
290usr/260sys/568real ms.
Pass 3: translated to C into
"/tmp/stapiArgLX/stap_e5886fa50499994e6a87aacdc43cd392_399.c" in
490usr/430sys/938real ms.
Pass 4: compiled C into "stap_e5886fa50499994e6a87aacdc43cd392_399.ko" in
3310usr/430sys/3714real ms.
Pass 5: starting run. ❶
read performed ❷
Pass 5: run completed in 10usr/40sys/73real ms. ❸
```

The last three lines of output (beginning with **Pass 5**) indicate that:

- ❶ SystemTap successfully created the instrumentation to probe the kernel and ran the instrumentation.
- ❷ SystemTap detected the specified event (in this case, A VFS read).
- ❸ SystemTap executed a valid handler (printed text and then closed it with no errors).

37.3. PRIVILEGES TO RUN SYSTEMTAP

Running SystemTap scripts requires elevated system privileges but, in some instances, non-privileged users might need to run SystemTap instrumentation on their machine.

To allow users to run SystemTap without root access, add users to **both** of these user groups:

stapdev

Members of this group can use **stap** to run SystemTap scripts, or **staprun** to run SystemTap instrumentation modules.

Running **stap** involves compiling SystemTap scripts into kernel modules and loading them into the kernel. This requires elevated privileges to the system, which are granted to **stapdev** members. Unfortunately, such privileges also grant effective root access to **stapdev** members. As such, only grant **stapdev** group membership to users who can be trusted with root access.

stapusr

Members of this group can only use **staprun** to run SystemTap instrumentation modules. In addition, they can only run those modules from the **/lib/modules/kernel_version/systemtap/** directory. This directory must be owned only by the root user, and must only be writable by the root user.

37.4. RUNNING SYSTEMTAP SCRIPTS

You can run SystemTap scripts from standard input or from a file.

Sample scripts that are distributed with the installation of SystemTap can be found in the **/usr/share/systemtap/examples** directory.

Prerequisites

1. SystemTap and the associated required kernel packages are installed as described in [Installing Systemtap](#).
2. To run SystemTap scripts as a normal user, add the user to the SystemTap groups:

```
# usermod --append --groups
stapdev,stapusr user-name
```

Procedure

- Run the SystemTap script:

- From standard input:

```
# echo "probe timer.s(1) {exit()}" | stap -
```

This command instructs **stap** to run the script passed by **echo** to standard input. To add **stap** options, insert them before the **-** character. For example, to make the results from this command more verbose, the command is:

```
# echo "probe timer.s(1) {exit()}" | stap -v -
```

- From a file:

```
# stap file_name
```

CHAPTER 38. CROSS-INSTRUMENTATION OF SYSTEMTAP

Cross-instrumentation of SystemTap is creating SystemTap instrumentation modules from a SystemTap script on one system to be used on another system that does not have SystemTap fully deployed.

38.1. SYSTEMTAP CROSS-INSTRUMENTATION

When you run a SystemTap script, a kernel module is built out of that script. SystemTap then loads the module into the kernel.

Normally, SystemTap scripts can run only on systems where SystemTap is deployed. To run SystemTap on ten systems, SystemTap needs to be deployed on all those systems. In some cases, this might be neither feasible nor desired. For example, corporate policy might prohibit you from installing packages that provide compilers or debug information on specific machines, which will prevent the deployment of SystemTap.

To work around this, use *cross-instrumentation*. Cross-instrumentation is the process of generating SystemTap instrumentation modules from a SystemTap script on one system to be used on another system. This process offers the following benefits:

- The kernel information packages for various machines can be installed on a single host machine.

IMPORTANT

Kernel packaging bugs may prevent the installation. In such cases, the **kernel-debuginfo** and **kernel-devel** packages for the *host system* and *target system* must match. If a bug occurs, report the bug at <https://bugzilla.redhat.com/>.

- Each *target machine* needs only one package to be installed to use the generated SystemTap instrumentation module: **systemtap-runtime**.

IMPORTANT

The *host system* must be the same architecture and running the same distribution of Linux as the *target system* in order for the built *instrumentation module* to work.

TERMINOLOGY

instrumentation module

The kernel module built from a SystemTap script; the SystemTap module is built on the *host system*, and will be loaded on the *target kernel* of the *target system*.

host system

The system on which the instrumentation modules (from SystemTap scripts) are compiled, to be loaded on *target systems*.

target system

The system in which the *instrumentation module* is being built (from SystemTap scripts).

target kernel

The kernel of the *target system*. This is the kernel that loads and runs the *instrumentation module*.

38.2. INITIALIZING CROSS-INSTRUMENTATION OF SYSTEMTAP

Initialize cross-instrumentation of SystemTap to build SystemTap instrumentation modules from a SystemTap script on one system and use them on another system that does not have SystemTap fully deployed.

Prerequisites

- SystemTap is installed on the *host system* as described in [Installing Systemtap](#).
- The **systemtap-runtime** package is installed on each *target system*:

```
# yum install systemtap-runtime
```

- Both the *host system* and *target system* are the same architecture.
- Both the *host system* and *target system* are running the same major version of Red Hat Enterprise Linux (such as Red Hat Enterprise Linux 8), they *can* be running different minor versions (such as 8.1 and 8.2).

IMPORTANT

Kernel packaging bugs may prevent multiple **kernel-debuginfo** and **kernel-devel** packages from being installed on one system. In such cases, the minor version for the *host system* and *target system* must match. If a bug occurs, report it at <https://bugzilla.redhat.com/>.

Procedure

1. Determine the kernel running on each *target system*:

```
$ uname -r
```

Repeat this step for each *target system*.

2. On the *host system*, install the *target kernel* and related packages for each *target system* by the method described in [Installing Systemtap](#).

3. Build an instrumentation module on the *host system*, copy this module to and run this module on on the *target system* either:

- a. Using remote implementation:

```
# stap --remote target_system script
```

This command remotely implements the specified script on the *target system*. You must ensure an SSH connection can be made to the *target system* from the *host system* for this to be successful.

- b. Manually:

- i. Build the instrumentation module on the *host system*:

```
# stap -r kernel_version script -m module_name -p 4
```

Here, *kernel_version* refers to the version of the *target kernel* determined in step 1, *script* refers to the script to be converted into an *instrumentation module*, and *module_name* is the desired name of the *instrumentation module*. The **-p4** option tells SystemTap to not load and run the compiled module.

- ii. Once the *instrumentation module* is compiled, copy it to the target system and load it using the following command:

```
# staprun module_name.ko
```

CHAPTER 39. MONITORING NETWORK ACTIVITY WITH SYSTEMTAP

You can use helpful example SystemTap scripts available in the `/usr/share/systemtap/testsuite/systemtap.examples/` directory, upon installing the **systemtap-testsuite** package, to monitor and investigate the network activity of your system.

39.1. PROFILING NETWORK ACTIVITY WITH SYSTEMTAP

You can use the **nettop.stp** example SystemTap script to profile network activity. The script tracks which processes are generating network traffic on the system, and provides the following information about each process:

PID

The ID of the listed process.

UID

User ID. A user ID of 0 refers to the root user.

DEV

Which ethernet device the process used to send or receive data (for example, eth0, eth1).

XMIT_PK

The number of packets transmitted by the process.

RECV_PK

The number of packets received by the process.

XMIT_KB

The amount of data sent by the process, in kilobytes.

RECV_KB

The amount of data received by the service, in kilobytes.

Prerequisites

- You have installed SystemTap as described in [Installing SystemTap](#).

Procedure

- Run the **nettop.stp** script:

```
# stap --example nettop.stp
```

The **nettop.stp** script provides network profile sampling every 5 seconds.

Output of the **nettop.stp** script looks similar to the following:

```
[...]
PID UID DEV XMIT_PK RECV_PK XMIT_KB RECV_KB COMMAND
0 0 eth0 0 5 0 0 swapper
11178 0 eth0 2 0 0 0 synergyc
PID UID DEV XMIT_PK RECV_PK XMIT_KB RECV_KB COMMAND
2886 4 eth0 79 0 5 0 cups-polld
11362 0 eth0 0 61 0 5 firefox
```

```

    0 0 eth0      3 32 0 3 swapper
2886 4 lo        4 4 0 0 cups-polld
11178 0 eth0     3 0 0 0 synergyc
  PID UID DEV   XMIT_PK RECV_PK XMIT_KB RECV_KB COMMAND
    0 0 eth0     0 6 0 0 swapper
2886 4 lo        2 2 0 0 cups-polld
11178 0 eth0     3 0 0 0 synergyc
3611 0 eth0     0 1 0 0 Xorg
  PID UID DEV   XMIT_PK RECV_PK XMIT_KB RECV_KB COMMAND
    0 0 eth0     3 42 0 2 swapper
11178 0 eth0    43 1 3 0 synergyc
11362 0 eth0     0 7 0 0 firefox
3897 0 eth0     0 1 0 0 multiload-apple

```

39.2. TRACING FUNCTIONS CALLED IN NETWORK SOCKET CODE WITH SYSTEMTAP

You can use the **socket-trace.stp** example SystemTap script to trace functions called from the kernel's `net/socket.c` file. This helps you identify, in finer detail, how each process interacts with the network at the kernel level.

Prerequisites

- You have installed SystemTap as described in [Installing SystemTap](#).

Procedure

- Run the **socket-trace.stp** script:

```
# stap --example socket-trace.stp
```

A 3-second excerpt of the output of the **socket-trace.stp** script looks similar to the following:

```

[...]
0 Xorg(3611): -> sock_poll
3 Xorg(3611): <- sock_poll
0 Xorg(3611): -> sock_poll
3 Xorg(3611): <- sock_poll
0 gnome-terminal(11106): -> sock_poll
5 gnome-terminal(11106): <- sock_poll
0 scim-bridge(3883): -> sock_poll
3 scim-bridge(3883): <- sock_poll
0 scim-bridge(3883): -> sys_socketcall
4 scim-bridge(3883): -> sys_recv
8 scim-bridge(3883): -> sys_recvfrom
12 scim-bridge(3883):-> sock_from_file
16 scim-bridge(3883):<- sock_from_file
20 scim-bridge(3883):-> sock_recvmsg
24 scim-bridge(3883):<- sock_recvmsg
28 scim-bridge(3883): <- sys_recvfrom
31 scim-bridge(3883): <- sys_recv
35 scim-bridge(3883): <- sys_socketcall
[...]
```

39.3. MONITORING NETWORK PACKET DROPS WITH SYSTEMTAP

The network stack in Linux can discard packets for various reasons. Some Linux kernels include a tracepoint, **kernel.trace("kfree_skb")**, which tracks where packets are discarded.

The **dropwatch.stp** SystemTap script uses **kernel.trace("kfree_skb")** to trace packet discards; the script summarizes what locations discard packets in every 5-second interval.

Prerequisites

- You have installed SystemTap as described in [Installing SystemTap](#).

Procedure

- Run the **dropwatch.stp** script:

```
# stap --example dropwatch.stp
```

Running the **dropwatch.stp** script for 15 seconds results in output similar to the following:

```
Monitoring for dropped packets
51 packets dropped at location 0xffffffff8024cd0f
2 packets dropped at location 0xffffffff8044b472
51 packets dropped at location 0xffffffff8024cd0f
1 packets dropped at location 0xffffffff8044b472
97 packets dropped at location 0xffffffff8024cd0f
1 packets dropped at location 0xffffffff8044b472
Stopping dropped packet monitor
```

NOTE

To make the location of packet drops more meaningful, see the **/boot/System.map-\$(uname -r)** file. This file lists the starting addresses for each function, enabling you to map the addresses in the output of the **dropwatch.stp** script to a specific function name. Given the following snippet of the **/boot/System.map-\$(uname -r)** file, the address **0xffffffff8024cd0f** maps to the function **unix_stream_recvmsg** and the address **0xffffffff8044b472** maps to the function **arp_rcv**:

```
[...]
ffffff8024c5cd T unlock_new_inode
ffffff8024c5da t unix_stream_sendmsg
ffffff8024c920 t unix_stream_recvmsg
ffffff8024cea1 t udp_v4_lookup_longway
[...]
ffffff8044addc t arp_process
ffffff8044b360 t arp_rcv
ffffff8044b487 t parp_redo
ffffff8044b48c t arp_solicit
[...]
```

CHAPTER 40. PROFILING KERNEL ACTIVITY WITH SYSTEMTAP

The following sections showcase scripts that profile kernel activity by monitoring function calls.

40.1. COUNTING FUNCTION CALLS WITH SYSTEMTAP

You can use the **functioncallcount.stp** SystemTap script to count specific kernel function calls. You can also use this script to target multiple kernel functions.

Prerequisites

- You have installed SystemTap as described in [Installing SystemTap](#).

Procedure

- Run the **functioncallcount.stp** script:

```
# stap --example functioncallcount.stp 'argument'
```

This script takes the targeted kernel function as an argument. You can use the argument wildcards to target multiple kernel functions up to a certain extent.

The output of the script, in alphabetical order, contains the names of the functions called and how many times it was called during the sample time.

Consider the following example:

```
# stap -w -v --example functioncallcount.stp "*"@mm*.c" -c /bin/true
```

where:

- **-w** : Suppresses warnings.
- **-v** : Makes the output of starting kernel visible.
- **-c command** : Tells SystemTap to count function calls during the execution of a command, in this example being **/bin/true**.

The output should look similar to the following:

```
[...]
__vma_link 97
__vma_link_file 66
__vma_link_list 97
__vma_link_rb 97
__xchg 103
add_page_to_active_list 102
add_page_to_inactive_list 19
add_to_page_cache 19
add_to_page_cache_lru 7
all_vm_events 6
alloc_pages_node 4630
alloc_slabmgmt 67
```

```
anon_vma_alloc 62
anon_vma_free 62
anon_vma_lock 66
anon_vma_prepare 98
anon_vma_unlink 97
anon_vma_unlock 66
arch_get_unmapped_area_topdown 94
arch_get_unmapped_exec_area 3
arch_unmap_area_topdown 97
atomic_add 2
atomic_add_negative 97
atomic_dec_and_test 5153
atomic_inc 470
atomic_inc_and_test 1
[...]
```

40.2. TRACING FUNCTION CALLS WITH SYSTEMTAP

You can use the **para-callgraph.stp** SystemTap script to trace function calls and function returns.

Prerequisites

- You have installed SystemTap as described in [Installing SystemTap](#).

Procedure

- Run the **para-callgraph.stp** script.

```
# stap --example para-callgraph.stp 'argument1' 'argument2'
```

The script **para-callgraph.stp** takes two command-line arguments:

1. The name of the function(s) whose entry/exit you'd like to trace.
2. An optional trigger function, which enables or disables tracing on a per-thread basis. Tracing in each thread will continue as long as the trigger function has not exited yet.

Consider the following example:

```
# stap -wv --example para-callgraph.stp 'kernel.function("*@fs/proc.c*")' 'kernel.function("vfs_read")' -
c "cat /proc/sys/vm/* || true"
```

where:

- **-w** : Suppresses warnings.
- **-v** : Makes the output of starting kernel visible.
- **-c *command*** : Tells SystemTap to count function calls during the execution of a command, in this example being **/bin/true**.

The output should look similar to the following:

```
[...]
```

```

267 gnome-terminal(2921): <-do_sync_read return=0xffffffffffff5
269 gnome-terminal(2921):<-vfs_read return=0xffffffffffff5
0 gnome-terminal(2921):->fput file=0xffff880111eebbc0
2 gnome-terminal(2921):<-fput
0 gnome-terminal(2921):->fget_light fd=0x3 fput_needed=0xffff88010544df54
3 gnome-terminal(2921):<-fget_light return=0xffff8801116ce980
0 gnome-terminal(2921):->vfs_read file=0xffff8801116ce980 buf=0xc86504 count=0x1000
pos=0xffff88010544df48
4 gnome-terminal(2921): ->rw_verify_area read_write=0x0 file=0xffff8801116ce980
ppos=0xffff88010544df48 count=0x1000
7 gnome-terminal(2921): <-rw_verify_area return=0x1000
12 gnome-terminal(2921): ->do_sync_read filp=0xffff8801116ce980 buf=0xc86504 len=0x1000
ppos=0xffff88010544df48
15 gnome-terminal(2921): <-do_sync_read return=0xffffffffffff5
18 gnome-terminal(2921):<-vfs_read return=0xffffffffffff5
0 gnome-terminal(2921):->fput file=0xffff8801116ce980

```

40.3. DETERMINING TIME SPENT IN KERNEL AND USER SPACE WITH SYSTEMTAP

You can use the **thread-times.stp** SystemTap script to determine the amount of time any given thread is spending in either the kernel or user-space.

Prerequisites

- You have installed SystemTap as described in [Installing SystemTap](#).

Procedure

- Run the **thread-times.stp** script:

```
# stap --example thread-times.stp
```

This script will display the top 20 processes taking up CPU time during a 5-second period, along with the total number of CPU ticks made during the sample. The output of this script also notes the percentage of CPU time each process used, as well as whether that time was spent in kernel space or user space.

```

tid  %user %kernel (of 20002 ticks)
0    0.00% 87.88%
32169 5.24% 0.03%
9815  3.33% 0.36%
9859  0.95% 0.00%
3611  0.56% 0.12%
9861  0.62% 0.01%
11106 0.37% 0.02%
32167 0.08% 0.08%
3897  0.01% 0.08%
3800  0.03% 0.00%
2886  0.02% 0.00%
3243  0.00% 0.01%
3862  0.01% 0.00%
3782  0.00% 0.00%
21767 0.00% 0.00%

```

```
2522 0.00% 0.00%
3883 0.00% 0.00%
3775 0.00% 0.00%
3943 0.00% 0.00%
3873 0.00% 0.00%
```

40.4. MONITORING POLLING APPLICATIONS WITH SYSTEMTAP

You can use **timeout.stp** SystemTap script to identify and monitor which applications are polling. Doing so allows you to track unnecessary or excessive polling, which helps you pinpoint areas for improvement in terms of CPU usage and power savings.

Prerequisites

- You have installed SystemTap as described in [Installing SystemTap](#).

Procedure

- Run the **timeout.stp** script:

```
# stap --example timeout.stp
```

This script will track how many times each application uses the following system calls over time:

- poll**
- select**
- epoll**
- itimer**
- futex**
- nanosleep**
- signal**

In this example output you can see which process used which system call and how many times.

```
uid | poll select  epoll itimer  futex nanosle  signal| process
28937 | 148793  0    0  4727 37288  0    0| firefox
22945 |  0 56949  0    1    0    0    0| scim-bridge
 0 |  0    0    0 36414  0    0    0| swapper
4275 | 23140  0    0    1    0    0    0| mixer_applet2
4191 |  0 14405  0    0    0    0    0| scim-launcher
22941 | 7908  1    0   62    0    0    0| gnome-terminal
4261 |  0    0    0    2    0 7622  0| escd
3695 |  0    0    0    0    0 7622  0| gdm-binary
3483 |  0 7206  0    0    0    0    0| dhcdbd
4189 | 6916  0    0    2    0    0    0| scim-panel-gtk
1863 | 5767  0    0    0    0    0    0| iscsid
```

40.5. TRACKING MOST FREQUENTLY USED SYSTEM CALLS WITH SYSTEMTAP

You can use the **topsys.stp** SystemTap script to list the top 20 system calls used by the system per 5-second interval. It also lists how many times each system call was used during that period.

Prerequisites

- You have installed SystemTap as described in [Installing SystemTap](#).

Procedure

- Run the **topsys.stp** script:

```
# stap --example topsys.stp
```

Consider the following example:

```
# stap -v --example topsys.stp
```

where `-v` makes the output of starting kernel visible.

The output should look similar to the following:

```
-----
      SYSCALL    COUNT
gettimeofday    1857
      read      1821
      ioctl     1568
      poll      1033
      close      638
      open       503
      select     455
      write      391
      writev     335
      futex      303
      recvmmsg   251
      socket     137
      clock_gettime 124
      rt_sigprocmask 121
      sendto     120
      setitimer   106
      stat        90
      time        81
      sigreturn   72
      fstat       66
-----
```

40.6. TRACKING SYSTEM CALL VOLUME PER PROCESS WITH SYSTEMTAP

You can use the **syscalls_by_proc.stp** SystemTap script to see which processes are performing the highest volume of system calls. It displays 20 processes performing the most of system calls.

Prerequisites

- You have installed SystemTap as described in [Installing SystemTap](#).

Procedure

- Run the **syscalls_by_proc.stp** script:

```
# stap --example syscalls_by_proc.stp
```

Output of the **syscalls_by_proc.stp** script looks similar to the following:

```
Collecting data... Type Ctrl-C to exit and display results
#SysCalls Process Name
1577    multiload-apple
692     synergyc
408     pcscd
376     mixer_applet2
299     gnome-terminal
293     Xorg
206     scim-panel-gtk
95      gnome-power-man
90      artsd
85      dhcdbd
84      scim-bridge
78      gnome-screensav
66      scim-launcher
[...]
```

CHAPTER 41. MONITORING DISK AND I/O ACTIVITY WITH SYSTEMTAP

The following sections showcase scripts that monitor disk and I/O activity.

41.1. SUMMARIZING DISK READ/WRITE TRAFFIC WITH SYSTEMTAP

You can use the **disktop.stp** SystemTap script to identify which processes are performing the heaviest disk reads and writes to the system.

Prerequisites

- You have installed SystemTap as described in [Installing SystemTap](#).

Procedure

- Run the **disktop.stp** script:

```
# stap --example disktop.stp
```

The script displays the top ten processes responsible for the heaviest reads or writes to a disk.

The output includes the following data per listed process:

UID

User ID. A user ID of **0** refers to the root user.

PID

The ID of the listed process.

PPID

The process ID of the listed process's parent process.

CMD

The name of the listed process.

DEVICE

Which storage device the listed process is reading from or writing to.

T

The type of action performed by the listed process, where **W** refers to write, and **R** refers to read.

BYTES

The amount of data read to or written from disk.

Output of the **disktop.stp** script looks similar to the following:

```
[...]
Mon Sep 29 03:38:28 2008 , Average: 19Kb/sec, Read: 7Kb, Write: 89Kb
UID  PID  PPID      CMD  DEVICE  T  BYTES
0  26319  26294    firefox  sda5  W   90229
0  2758   2757  pam_timestamp_c  sda5  R    8064
0  2885    1    cupsd  sda5  W    1678
Mon Sep 29 03:38:38 2008 , Average: 1Kb/sec, Read: 7Kb, Write: 1Kb
```

```

UID    PID    PPID      CMD    DEVICE  T  BYTES
0    2758    2757    pam_timestamp_c    sda5  R    8064
0    2885      1      cupsd    sda5  W    1678

```

41.2. TRACKING I/O TIME FOR EACH FILE READ OR WRITE WITH SYSTEMTAP

You can use the **iotime.stp** SystemTap script to monitor the amount of time it takes for each process to read from or write to any file. This helps you to determine what files are slow to load on a system.

Prerequisites

- You have installed SystemTap as described in [Installing SystemTap](#).

Procedure

- Run the **iotime.stp** script:

```
# stap --example iotime.stp
```

The script tracks each time a system call opens, closes, reads from, and writes to a file. For each file any system call accesses, It counts the number of microseconds it takes for any reads or writes to finish and tracks the amount of data , in bytes, read from or written to the file.

The output contains:

- A timestamp, in microseconds
- Process ID and process name
- An **access** or **iotime** flag
- The file accessed

If a process was able to read or write any data, a pair of access and **iotime** lines should appear together. The access line refers to the time that a given process started accessing a file. The end of the access line will show the amount of data read or written. The **iotime** line will show the amount of time, in microseconds, that the process took in order to perform the read or write.

Output of the **iotime.stp** script looks similar to the following:

```

[...]
825946 3364 (NetworkManager) access /sys/class/net/eth0/carrier read: 8190 write: 0
825955 3364 (NetworkManager) iotime /sys/class/net/eth0/carrier time: 9
[...]
117061 2460 (pcscd) access /dev/bus/usb/003/001 read: 43 write: 0
117065 2460 (pcscd) iotime /dev/bus/usb/003/001 time: 7
[...]
3973737 2886 (sendmail) access /proc/loadavg read: 4096 write: 0
3973744 2886 (sendmail) iotime /proc/loadavg time: 11
[...]

```

41.3. TRACKING CUMULATIVE I/O WITH SYSTEMTAP

You can use the **traceio.stp** SystemTap script to track the cumulative amount of I/O to the system.

Prerequisites

- You have installed SystemTap as described in [Installing SystemTap](#).

Procedure

- Run the **traceio.stp** script:

```
# stap --example traceio.stp
```

The script prints the top ten executables generating I/O traffic over time. It also tracks the cumulative amount of I/O reads and writes done by those executables. This information is tracked and printed out in 1-second intervals, and in descending order.

Output of the **traceio.stp** script looks similar to the following:

```
[...]
  Xorg r: 583401 KiB w:    0 KiB
 floaters r:   96 KiB w:  7130 KiB
 multiload-apple r:   538 KiB w:   537 KiB
  sshd r:   71 KiB w:   72 KiB
 pam_timestamp_c r:   138 KiB w:    0 KiB
  staprun r:   51 KiB w:   51 KiB
  snmpd r:   46 KiB w:    0 KiB
  pcscd r:   28 KiB w:    0 KiB
 irqbalance r:   27 KiB w:    4 KiB
  cupsd r:    4 KiB w:   18 KiB
  Xorg r: 588140 KiB w:    0 KiB
 floaters r:   97 KiB w:  7143 KiB
 multiload-apple r:   543 KiB w:   542 KiB
  sshd r:   72 KiB w:   72 KiB
 pam_timestamp_c r:   138 KiB w:    0 KiB
  staprun r:   51 KiB w:   51 KiB
  snmpd r:   46 KiB w:    0 KiB
  pcscd r:   28 KiB w:    0 KiB
 irqbalance r:   27 KiB w:    4 KiB
  cupsd r:    4 KiB w:   18 KiB
```

41.4. MONITORING I/O ACTIVITY ON A SPECIFIC DEVICE WITH SYSTEMTAP

You can use the **traceio2.stp** SystemTap script to monitor I/O activity on a specific device.

Prerequisites

- You have installed SystemTap as described in [Installing SystemTap](#).

Procedure

- Run the **traceio2.stp** script.

```
# stap --example traceio2.stp 'argument'
```

This script takes the whole device number as an argument. To find this number you can use:

```
# stat -c "0x%D" directory
```

Where *directory* is located on the device you want to monitor.

The output contains following:

- The name and ID of any process performing a read or write
- The function it is performing (**vfs_read** or **vfs_write**)
- The kernel device number

Consider following output of **# stap traceio2.stp 0x805**

```
[...]
synergyc(3722) vfs_read 0x800005
synergyc(3722) vfs_read 0x800005
cupsd(2889) vfs_write 0x800005
cupsd(2889) vfs_write 0x800005
cupsd(2889) vfs_write 0x800005
[...]
```

41.5. MONITORING READS AND WRITES TO A FILE WITH SYSTEMTAP

You can use the **inodewatch.stp** SystemTap script to monitor reads from and writes to a file in real time.

Prerequisites

- You have installed SystemTap as described in [Installing SystemTap](#).

Procedure

- Run the **inodewatch.stp** script.

```
# stap --example inodewatch.stp 'argument1' 'argument2' 'argument3'
```

The script **inodewatch.stp** takes three command-line arguments:

1. The file's major device number.
2. The file's minor device number.
3. The file's inode number.

You can get these numbers using:

```
# stat -c '%D %i' filename
```

Where *filename* is an absolute path.

Consider following example:

```
# stat -c '%D %i' /etc/crontab
```

The output should look like:

```
805 1078319
```

where:

- **805** is the base-16 (hexadecimal) device number. The last two digits are the minor device number, and the remaining digits are the major number.
- **1078319** is the inode number.

To start monitoring **/etc/crontab**, run:

```
# stap inodewatch.stp 0x8 0x05 1078319
```

In the first two arguments you must use 0x prefixes for base-16 numbers.

The output contains following:

- The name and ID of any process performing a read or write
- The function it is performing (**vfs_read** or **vfs_write**)
- The kernel device number

The output of this example should look like:

```
cat(16437) vfs_read 0x8000005/1078319
cat(16437) vfs_read 0x8000005/1078319
```

CHAPTER 42. ANALYZING SYSTEM PERFORMANCE WITH BPF COMPILER COLLECTION

As a system administrator, you can use the BPF Compiler Collection (BCC) library to create tools for analyzing the performance of your Linux operating system and gathering information, which could be difficult to obtain through other interfaces.

42.1. AN INTRODUCTION TO BCC

BPF Compiler Collection (BCC) is a library, which facilitates the creation of the extended Berkeley Packet Filter (eBPF) programs. The main utility of eBPF programs is analyzing OS performance and network performance without experiencing overhead or security issues.

BCC removes the need for users to know deep technical details of eBPF, and provides many out-of-the-box starting points, such as the **bcc-tools** package with pre-created eBPF programs.

NOTE

The eBPF programs are triggered on events, such as disk I/O, TCP connections, and process creations. It is unlikely that the programs should cause the kernel to crash, loop or become unresponsive because they run in a safe virtual machine in the kernel.

42.2. INSTALLING THE BCC-TOOLS PACKAGE

This section describes how to install the **bcc-tools** package, which also installs the BPF Compiler Collection (BCC) library as a dependency.

Prerequisites

- An active [Red Hat Enterprise Linux subscription](#)
- An [enabled repository](#) containing the **bcc-tools** package
- [Updated kernel](#)
- Root permissions

Procedure

1. Install **bcc-tools**:

```
# yum install bcc-tools
```

The BCC tools are installed in the **/usr/share/bcc/tools/** directory.

2. Optionally, inspect the tools:

```
# ll /usr/share/bcc/tools/
...
-rwxr-xr-x. 1 root root 4198 Dec 14 17:53 dcsnoop
-rwxr-xr-x. 1 root root 3931 Dec 14 17:53 dcstat
-rwxr-xr-x. 1 root root 20040 Dec 14 17:53 deadlock_detector
-rw-r--r--. 1 root root 7105 Dec 14 17:53 deadlock_detector.c
```

```
drwxr-xr-x. 3 root root 8192 Mar 11 10:28 doc
-rwxr-xr-x. 1 root root 7588 Dec 14 17:53 execsnoop
-rwxr-xr-x. 1 root root 6373 Dec 14 17:53 ext4dist
-rwxr-xr-x. 1 root root 10401 Dec 14 17:53 ext4slower
...
```

The **doc** directory in the listing above contains documentation for each tool.

42.3. USING SELECTED BCC-TOOLS FOR PERFORMANCE ANALYSES

This section describes how to use certain pre-created programs from the BPF Compiler Collection (BCC) library to efficiently and securely analyze the system performance on the per-event basis. The set of pre-created programs in the BCC library can serve as examples for creation of additional programs.

Prerequisites

- [Installed bcc-tools package](#)
- Root permissions

Using execsnoop to examine the system processes

1. Execute the **execsnoop** program in one terminal:

```
# /usr/share/bcc/tools/execsnoop
```

2. In another terminal execute for example:

```
$ ls /usr/share/bcc/tools/doc/
```

The above creates a short-lived process of the **ls** command.

3. The terminal running **execsnoop** shows the output similar to the following:

```
PCOMM PID  PPID  RET ARGS
ls 8382 8287 0 /usr/bin/ls --color=auto /usr/share/bcc/tools/doc/
...
```

The **execsnoop** program prints a line of output for each new process, which consumes system resources. It even detects processes of programs that run very shortly, such as **ls**, and most monitoring tools would not register them.

The **execsnoop** output displays the following fields:

- **PCOMM** - The parent process name. (**ls**)
- **PID** - The process ID. (**8382**)
- **PPID** - The parent process ID. (**8287**)
- **RET** - The return value of the **exec()** system call (**0**), which loads program code into new processes.
- **ARGS** - The location of the started program with arguments.

To see more details, examples, and options for **execsnoop**, refer to the **/usr/share/bcc/tools/doc/execsnoop_example.txt** file.

For more information about **exec()**, see **exec(3)** manual pages.

Using opensnoop to track what files a command opens

1. Execute the **opensnoop** program in one terminal:

```
# /usr/share/bcc/tools/opensnoop -n uname
```

The above prints output for files, which are opened only by the process of the **uname** command.

2. In another terminal execute:

```
$ uname
```

The command above opens certain files, which are captured in the next step.

3. The terminal running **opensnoop** shows the output similar to the following:

```
PID  COMM  FD ERR PATH
8596  uname  3  0  /etc/ld.so.cache
8596  uname  3  0  /lib64/libc.so.6
8596  uname  3  0  /usr/lib/locale/locale-archive
...
```

The **opensnoop** program watches the **open()** system call across the whole system, and prints a line of output for each file that **uname** tried to open along the way.

The **opensnoop** output displays the following fields:

- **PID** - The process ID. (**8596**)
- **COMM** - The process name. (**uname**)
- **FD** - The file descriptor - a value that **open()** returns to refer to the open file. (**3**)
- **ERR** - Any errors.
- **PATH** - The location of files that **open()** tried to open.
If a command tries to read a non-existent file, then the **FD** column returns **-1** and the **ERR** column prints a value corresponding to the relevant error. As a result, **opensnoop** can help you identify an application that does not behave properly.

To see more details, examples, and options for **opensnoop**, refer to the **/usr/share/bcc/tools/doc/opensnoop_example.txt** file.

For more information about **open()**, see **open(2)** manual pages.

Using biotop to examine the I/O operations on the disk

1. Execute the **biotop** program in one terminal:

```
# /usr/share/bcc/tools/biotop 30
```

The command enables you to monitor the top processes, which perform I/O operations on the disk. The argument ensures that the command will produce a 30 second summary.

NOTE

When no argument provided, the output screen by default refreshes every 1 second.

2. In another terminal execute for example :

```
# dd if=/dev/vda of=/dev/zero
```

The command above reads the content from the local hard disk device and writes the output to the **/dev/zero** file. This step generates certain I/O traffic to illustrate **biotop**.

3. The terminal running **biotop** shows the output similar to the following:

```
PID  COMM      D MAJ MIN DISK   I/O Kbytes  AVGms
9568 dd        R 252 0  vda   16294 14440636.0 3.69
48  kswapd0   W 252 0  vda    1763 120696.0 1.65
7571 gnome-shell R 252 0  vda     834 83612.0 0.33
1891 gnome-shell R 252 0  vda    1379 19792.0 0.15
7515 Xorg       R 252 0  vda     280 9940.0 0.28
7579 llvmpipe-1 R 252 0  vda     228 6928.0 0.19
9515 gnome-control-c R 252 0  vda      62 6444.0 0.43
8112 gnome-terminal- R 252 0  vda      67 2572.0 1.54
7807 gnome-software R 252 0  vda      31 2336.0 0.73
9578 awk       R 252 0  vda      17 2228.0 0.66
7578 llvmpipe-0 R 252 0  vda     156 2204.0 0.07
9581 pgrep      R 252 0  vda      58 1748.0 0.42
7531 InputThread R 252 0  vda      30 1200.0 0.48
7504 gdbus     R 252 0  vda       3 1164.0 0.30
1983 llvmpipe-1 R 252 0  vda      39 724.0 0.08
1982 llvmpipe-0 R 252 0  vda      36 652.0 0.06
...
```

The **biotop** output displays the following fields:

- **PID** - The process ID. (**9568**)
- **COMM** - The process name. (**dd**)
- **DISK** - The disk performing the read operations. (**vda**)
- **I/O** - The number of read operations performed. (16294)
- **Kbytes** - The amount of Kbytes reached by the read operations. (14,440,636)
- **AVGms** - The average I/O time of read operations. (3.69)

To see more details, examples, and options for **biotop**, refer to the **/usr/share/bcc/tools/doc/biotop_example.txt** file.

For more information about **dd**, see **dd(1)** manual pages.

Using **xfsslower** to expose unexpectedly slow file system operations

1. Execute the **xfsslower** program in one terminal:

```
# /usr/share/bcc/tools/xfsslower 1
```

The command above measures the time the XFS file system spends in performing read, write, open or sync (**fsync**) operations. The **1** argument ensures that the program shows only the operations that are slower than 1 ms.

NOTE

When no arguments provided, **xfsslower** by default displays operations slower than 10 ms.

2. In another terminal execute, for example, the following:

```
$ vim text
```

The command above creates a text file in the **vim** editor to initiate certain interaction with the XFS file system.

3. The terminal running **xfsslower** shows something similar upon saving the file from the previous step:

```
TIME    COMM      PID  T BYTES  OFF_KB  LAT(ms)  FILENAME
13:07:14 b'bash'   4754  R 256    0       7.11 b'vim'
13:07:14 b'vim'   4754  R 832    0       4.03 b'libgpm.so.2.1.0'
13:07:14 b'vim'   4754  R 32     20      1.04 b'libgpm.so.2.1.0'
13:07:14 b'vim'   4754  R 1982   0       2.30 b'vimrc'
13:07:14 b'vim'   4754  R 1393   0       2.52 b'getsriptPlugin.vim'
13:07:45 b'vim'   4754  S 0      0      6.71 b'text'
13:07:45 b'pool'  2588  R 16     0       5.58 b'text'
...
```

Each line above represents an operation in the file system, which took more time than a certain threshold. **xfsslower** is good at exposing possible file system problems, which can take form of unexpectedly slow operations.

The **xfsslower** output displays the following fields:

- **COMM** - The process name. (**b'bash'**)
- **T** - The operation type. (**R**)
 - Read
 - Write
 - Sync
- **OFF_KB** - The file offset in KB. (0)
- **FILENAME** - The file being read, written, or synced.

To see more details, examples, and options for **xfsslower**, refer to the **/usr/share/bcc/tools/doc/xfsslower_example.txt** file.

For more information about **fsync**, see **fsync(2)** manual pages.
